Introduction	ix
About this publication	ix
Types of users	ix
Assumptions about your locale	ix
What's new in spatial data for IBM Informix, Version 11.70	x
Example code conventions	xi
Additional documentation	xi
Compliance with industry standards	xii
Syntax diagrams	xii
How to read a command-line syntax diagram	xiii
Keywords and punctuation	xiv
Identifiers and names.	xiv
How to provide documentation feedback	xv
Chapter 1. Getting started with spatial data	1-1
Comparison of spatial and geodetic data	1-2
Overview of using spatial data	1-2
Preparing to use spatial data	1-3
Sbspaces for spatial data	1-4
The spatial_references table	1-5
The structure of the spatial_references table	1-5
Select a false origin and system units	1-6
Work with spatial tables	1-7
Create a spatial table	1-7
Insert data into a spatial column	1-9
Create a spatial index	1-11
Update values in a spatial column	1-11
Perform spatial queries	1-12
Optimize spatial queries	1-12
Spatial data replication	1-13
The IBM Informix Web Feature Service	1-14
Chapter 2. Spatial data types	2-1
Properties of spatial data types	2-1
Interior, boundary, and exterior	2-2
Simple or nonsimple	2-2
Empty or not empty	2-3
Number of points	2-3
Envelope	2-3
Dimension	2-3
Z coordinates	2-4
Measures	2-4
Spatial reference system	2-4
ST_Point data type.	2-4
ST_LineString data type	2-5
ST_Polygon data type.	2-6
ST_MultiPoint data type	2-7
ST_MultiLineString data type	2-7
ST_MultiPolygon data type	2-8
Locale override	2-9
Spatial data types with SPL.	2-9
Chapter 3. Data exchange formats	3-1
Well-known text representation	3-1
Well-known binary representation	3-1

ESRI shape representation	3-2
Geography Markup Language representation	3-3
Keyhole Markup Language representation	3-4
Chapter 4. R-tree indexes	4-1
Syntax for creating an R-tree index	4-1
Bottom-up versus top-down index builds	4-3
Functional R-tree indexes	4-4
Verify that the index is correctly built	4-4
The spatial operator class ST_Geometry_Ops	4-4
How spatial operators use R-tree indexes	4-5
Chapter 5. Run parallel queries	5-1
Parallel query execution infrastructure	5-1
Resolve problems with SE_MetadataInit()	5-1
Execute parallel queries	5-1
Chapter 6. Estimate your spatial data	6-1
Estimating the storage space for the table	6-1
Estimate the size of the spatial column	6-1
Estimate the size of non-spatial columns	6-2
Estimate dbspace overhead requirements	6-2
Estimating the smart large object storage space	6-3
Estimating the size of spatial indexes	6-3
Chapter 7. Determine spatial relationships and transform geometries	7-1
Functions that determine spatial relationships.	7-1
The ST_Equals() function	7-1
The ST_Disjoint() function	7-2
The ST_Intersects() function.	7-2
The ST_Touches() function	7-3
The ST_Overlaps() function	7-4
The ST_Crosses() function	7-4
The ST_Within() function	7-5
The ST_Contains() function	7-6
Functions that produce a new geometry	7-7
The ST_Intersection() function	7-7
The ST_Difference() function	7-8
The ST_Union() function.	7-9
The ST_SymDifference() function	7-10
The SE_Dissolve() function.	7-11
Functions that transform geometries	7-12
The ST_Buffer function	7-12
The SE_LocateAlong() function	7-13
The SE_LocateBetween() function	7-14
The ST_ConvexHull() function	7-14
The SE_Generalize() function	7-15
The Dimensionally Extended 9 Intersection Model.	7-15
The ST_Equals() function	7-17
The ST_Disjoint() function	7-17
The ST_Intersects() function	7-17
The ST_Touches() function.	7-18
The ST_Overlaps() function	7-19
The ST_Crosses() function	7-20
The ST_Within() function	7-20
The ST_Contains() function	7-21
Chapter 8. Spatial functions	8-1
Summary of spatial functions by task type.	8-1
The ST_Area() function	8-9

Introduction

This introduction provides an overview of the information in this publication and describes the conventions it uses.

About this publication

This publication contains information to assist you in using the IBM® Informix® spatial extension with IBM Informix.

The IBM Informix spatial extension adds custom data types and supporting routines to the server.

This section discusses the organization of the publication, the intended audience, and the associated software products that you must have to develop and use the IBM Informix spatial extension. General information about the Informix spatial extension is available at <http://www.ibm.com/software/data/informix/blades/spatial/>.

Types of users

This publication is written for the following audience:

- Developers who design the tables to hold spatial information in IBM Informix databases
- Developers who write applications to access spatial information stored in IBM Informix databases

Assumptions about your locale

IBM Informix products can support many languages, cultures, and code sets. All the information related to character set, collation and representation of numeric data, currency, date, and time that is used by a language within a given territory and encoding is brought together in a single environment, called a Global Language Support (GLS) locale.

The IBM Informix OLE DB Provider follows the ISO string formats for date, time, and money, as defined by the Microsoft OLE DB standards. You can override that default by setting an Informix environment variable or registry entry, such as **DBDATE**.

If you use Simple Network Management Protocol (SNMP) in your Informix environment, note that the protocols (SNMPv1 and SNMPv2) recognize only English code sets. For more information, see the topic about GLS and SNMP in the *IBM Informix SNMP Subagent Guide*.

The examples in this publication are written with the assumption that you are using one of these locales: en_us.8859-1 (ISO 8859-1) on UNIX platforms or en_us.1252 (Microsoft 1252) in Windows environments. These locales support U.S. English format conventions for displaying and entering date, time, number, and currency values. They also support the ISO 8859-1 code set (on UNIX and Linux) or the Microsoft 1252 code set (on Windows), which includes the ASCII code set plus many 8-bit characters such as é, è, and ñ.

You can specify another locale if you plan to use characters from other locales in your data or your SQL identifiers, or if you want to conform to other collation rules for character data.

For instructions about how to specify locales, additional syntax, and other considerations related to GLS locales, see the *IBM Informix GLS User's Guide*.

What's new in spatial data for IBM Informix, Version 11.70

This publication includes information about new features and changes in existing functionality.

The following changes and enhancements are relevant to this publication. For a complete list of what's new in this release, see the release notes or the information center at http://publib.boulder.ibm.com/infocenter/idshelp/v117/topic/com.ibm.po.doc/new_features.htm.

Table 1. What's new for the IBM Informix Spatial Data User's Guide for 11.70.xC6

Overview	Reference
<p>Additional functions for spatial data</p> <p>The spatial data extension has new functions from the ESRI SDE 10.1 libraries. Some of the new functions support the OpenGIS and ISO/SQLMM standards and replace deprecated functions that are extensions to the standards. Additional new functions support overlapping IDs for spatial referencing definitions.</p>	<p>"The ST_DistanceToPoint() function" on page 8-36</p> <p>"The ST_PointAtDistance() function" on page 8-91</p> <p>Chapter 8, "Spatial functions," on page 8-1</p> <p>"The SE_CreateSrtxt() function" on page 8-27</p> <p>"The SE_CreateSrtxtList() function" on page 8-29</p> <p>"The SE_CreateSrtxtCount() function" on page 8-28</p>

Table 2. What's new for the IBM Informix Spatial Data User's Guide for 11.70.xC1

Overview	Reference
<p>Spatial data type and functions are built in and automatically registered</p> <p>You can use the data types and functions of the spatial extension (which was formerly known as the Spatial DataBlade[®] module) without performing some of the previously required prerequisites tasks, such as installing or registering the spatial extension. The sbspace to store spatial data and statistics information is also created automatically, if the SBSPACENAME and SYSSBSPACENAME configuration parameter are not already set.</p>	<p>"Preparing to use spatial data" on page 1-3</p>

Table 2. What's new for the IBM Informix Spatial Data User's Guide for 11.70.xC1 (continued)

Overview	Reference
<p>New editions and product names</p> <p>IBM Informix Dynamic Server editions were withdrawn and new Informix editions are available. Some products were also renamed. The publications in the Informix library pertain to the following products:</p> <ul style="list-style-type: none"> • IBM Informix database server, formerly known as IBM Informix Dynamic Server (IDS) • IBM OpenAdmin Tool (OAT) for Informix, formerly known as OpenAdmin Tool for Informix Dynamic Server (IDS) • IBM Informix SQL Warehousing Tool, formerly known as Informix Warehouse Feature 	<p>For more information about the Informix product family, go to http://www.ibm.com/software/data/informix/.</p>

Example code conventions

Examples of SQL code occur throughout this publication. Except as noted, the code is not specific to any single IBM Informix application development tool.

If only SQL statements are listed in the example, they are not delimited by semicolons. For instance, you might see the code in the following example:

```
CONNECT TO stores_demo
...

DELETE FROM customer
  WHERE customer_num = 121
...

COMMIT WORK
DISCONNECT CURRENT
```

To use this SQL code for a specific product, you must apply the syntax rules for that product. For example, if you are using an SQL API, you must use EXEC SQL at the start of each statement and a semicolon (or other appropriate delimiter) at the end of the statement. If you are using DB–Access, you must delimit multiple statements with semicolons.

Tip: Ellipsis points in a code example indicate that more code would be added in a full application, but it is not necessary to show it to describe the concept being discussed.

For detailed directions on using SQL statements for a particular application development tool or SQL API, see the documentation for your product.

Additional documentation

Documentation about this release of IBM Informix products is available in various formats.

You can access or install the product documentation from the Quick Start Guide CD that is shipped with Informix products. To get the most current information, see the Informix information centers at ibm.com[®]. You can access the information centers and other Informix technical information such as technotes, white papers, and IBM Redbooks[®] publications online at <http://www.ibm.com/software/data/sw-library/>.

Compliance with industry standards

IBM Informix products are compliant with various standards.

IBM Informix SQL-based products are fully compliant with SQL-92 Entry Level (published as ANSI X3.135-1992), which is identical to ISO 9075:1992. In addition, many features of IBM Informix database servers comply with the SQL-92 Intermediate and Full Level and X/Open SQL Common Applications Environment (CAE) standards.

The IBM Informix Geodetic DataBlade Module supports a subset of the data types from the *Spatial Data Transfer Standard (SDTS)—Federal Information Processing Standard 173*, as referenced by the document *Content Standard for Geospatial Metadata*, Federal Geographic Data Committee, June 8, 1994 (FGDC Metadata Standard).

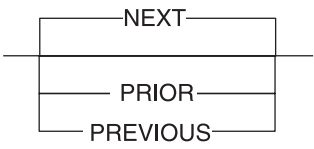

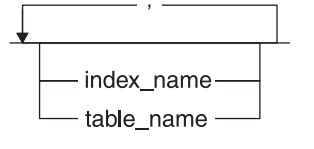

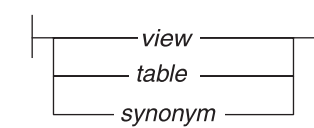

Syntax diagrams

Syntax diagrams use special components to describe the syntax for statements and commands.

Table 3. Syntax Diagram Components

Component represented in PDF	Component represented in HTML	Meaning
	>>-----	Statement begins.
	----->	Statement continues on next line.
	>-----	Statement continues from previous line.
	-----><	Statement ends.
	-----SELECT-----	Required item.
	---+-----+--- '-----LOCAL-----'	Optional item.
	---+-----ALL-----+--- +--DISTINCT-----+ '---UNIQUE-----'	Required item with choice. Only one item must be present.
	---+-----+--- +--FOR UPDATE-----+ '--FOR READ ONLY--'	Optional items with choice are shown below the main line, one of which you might specify.

Table 3. Syntax Diagram Components (continued)

Component represented in PDF	Component represented in HTML	Meaning
	<pre> .---NEXT----- -----+-----+----- +---PRIOR-----+ '---PREVIOUS-----' </pre>	The values below the main line are optional, one of which you might specify. If you do not specify an item, the value above the line is used by default.
	<pre> .-----,----- v----- ----- -----+-----+----- +---index_name---+ '---table_name---' </pre>	Optional items. Several items are allowed; a comma must precede each repetition.
	<pre>>>>- Table Reference -><</pre>	Reference to a syntax segment.
<p>Table Reference</p> 	<pre> Table Reference ---+-----view-----+--- +-----table-----+ '-----synonym-----' </pre>	Syntax segment.

How to read a command-line syntax diagram

Command-line syntax diagrams use similar elements to those of other syntax diagrams.

Some of the elements are listed in the table in Syntax Diagrams.

Creating a no-conversion job

```

>>>-onpladm create job-job-[-p-project]- -n- -d-device- -D-database->>>
                    
```

```

>>>-t-table->>>
                    
```

```

>>>-[-S-server- [-T-target-] Setting the Run Mode (1)->>>
                    
```

Notes:

1 See page Z-1

This diagram has a segment named “Setting the Run Mode,” which according to the diagram footnote is on page Z-1. If this was an actual cross-reference, you would find this segment on the first page of Appendix Z. Instead, this segment is shown in the following segment diagram. Notice that the diagram uses segment start and end components.

Setting the run mode:

To see how to construct a command correctly, start at the upper left of the main diagram. Follow the diagram to the right, including the elements that you want. The elements in this diagram are case-sensitive because they illustrate utility syntax. Other types of syntax, such as SQL, are not case-sensitive.

The Creating a No-Conversion Job diagram illustrates the following steps:

1. Type **onpladm create job** and then the name of the job.
2. Optionally, type **-p** and then the name of the project.
3. Type the following required elements:
 - **-n**
 - **-d** and the name of the device
 - **-D** and the name of the database
 - **-t** and the name of the table
4. Optionally, you can choose one or more of the following elements and repeat them an arbitrary number of times:
 - **-S** and the server name
 - **-T** and the target server name
 - The run mode. To set the run mode, follow the Setting the Run Mode segment diagram to type **-f**, optionally type **d**, **p**, or **a**, and then optionally type **l** or **u**.
5. Follow the diagram to the terminator.

Keywords and punctuation

Keywords are words reserved for statements and all commands except system-level commands.

When a keyword appears in a syntax diagram, it is shown in uppercase letters. When you use a keyword in a command, you can write it in uppercase or lowercase letters, but you must spell the keyword exactly as it appears in the syntax diagram.

You must also use any punctuation in your statements and commands exactly as shown in the syntax diagrams.

Identifiers and names

Variables serve as placeholders for identifiers and names in the syntax diagrams and examples.

You can replace a variable with an arbitrary name, identifier, or literal, depending on the context. Variables are also used to represent complex syntax elements that are expanded in additional syntax diagrams. When a variable appears in a syntax diagram, an example, or text, it is shown in *lowercase italic*.

The following syntax diagram uses variables to illustrate the general form of a simple SELECT statement.

►—SELECT—*column_name*—FROM—*table_name*—◄

When you write a SELECT statement of this form, you replace the variables *column_name* and *table_name* with the name of a specific column and table.

How to provide documentation feedback

You are encouraged to send your comments about IBM Informix user documentation.

Use one of the following methods:

- Send email to docinf@us.ibm.com.
- In the Informix information center, which is available online at <http://www.ibm.com/software/data/sw-library/>, open the topic that you want to comment on. Click the feedback link at the bottom of the page, fill out the form, and submit your feedback.
- Add comments to topics directly in the information center and read comments that were added by other users. Share information about the product documentation, participate in discussions with other users, rate topics, and more!

Feedback from all methods is monitored by the team that maintains the user documentation. The feedback methods are reserved for reporting errors and omissions in the documentation. For immediate help with a technical problem, contact IBM Technical Support at <http://www.ibm.com/planetwide/>.

We appreciate your suggestions.

Chapter 1. Getting started with spatial data

These topics introduce the IBM Informix spatial extension data types and routines, describe how to use the **spatial_references** table, and explain how to create a table with a spatial column and insert data into it.

IBM Informix spatial data types embed a geographic information system (GIS) within the IBM Informix database server. IBM Informix spatial data types implement the Open GIS Consortium, Inc. (OpenGIS, or OGC) SQL3 specification of abstract data types (ADTs). These data types can store spatial data such as the location of a landmark, a street, or a parcel of land. IBM Informix spatial data types also conforms to the OpenGIS Simple Features Specification for SQL Revision 1.1.

The GIS of the past were spatially centric and focused on gathering spatial data and attaching non-spatial attribute data to it. The IBM Informix spatial data types integrate spatial and non-spatial data, providing a seamless point of access using SQL (Structured Query Language).

You use specialized spatial data type functions to compare the values in spatial columns to determine if the values intersect, overlap, or are related in many different ways. These functions can answer questions like, "Is this school within five miles of a hazardous waste site?" An application programmer can use an SQL query to join a table storing sensitive sites such as schools, playgrounds, and hospitals to another table containing the locations of hazardous sites and return a list of sensitive areas at risk. For example, the following figure shows that a school and hospital lie within the five-mile radius of two hazardous site locations and the nursing home lies safely outside both radii.

Figure 1-1. Determining whether sensitive sites are within dangerous areas

You use the **ST_Overlaps()** function to evaluate whether the polygon representing the building footprint of the school overlaps the circular polygon that represents the five-mile radius of a hazardous waste site. The building footprints of the

school, hospital, and nursing home are stored in the ST_Polygon data type and the location of each hazardous waste site is stored in an ST_Point type.

Comparison of spatial and geodetic data

The IBM Informix spatial extension and the IBM Informix Geodetic DataBlade Module both manage GIS data in an IBM Informix database.

These products use different core technologies that solve different problems and complement each other:

- The IBM Informix Geodetic DataBlade Module treats the Earth as a globe. It uses a latitude and longitude coordinate system on an ellipsoidal Earth model. Geometric operations are precise regardless of location. The Geodetic DataBlade module is best used for global data sets and applications, such as satellite imagery repositories.
- The IBM Informix spatial extension treats the Earth as a flat map. It uses planimetric (flat-plane) geometry, which means that it approximates the round surface of the Earth by projecting it onto flat planes using various transformations. This leads to some distortion around the edges of the map. The IBM Informix spatial extension is best used for regional data sets and applications, such as those shown in the examples in this publication.

Overview of using spatial data

You can create tables that contain Informix spatial data type columns. You can insert and store geographic features in the spatial columns.

The following figure shows the architecture for IBM Informix and spatial applications. The IBM Informix server can communicate to Java™ applications through the Informix JDBC Driver, C applications through the IBM Informix ODBC Driver, directly with ESQ/C applications and DB-Access, and to ESRI application servers through the IBM Informix ODBC Driver. ESRI application servers communicate to license managers and ESRI clients.

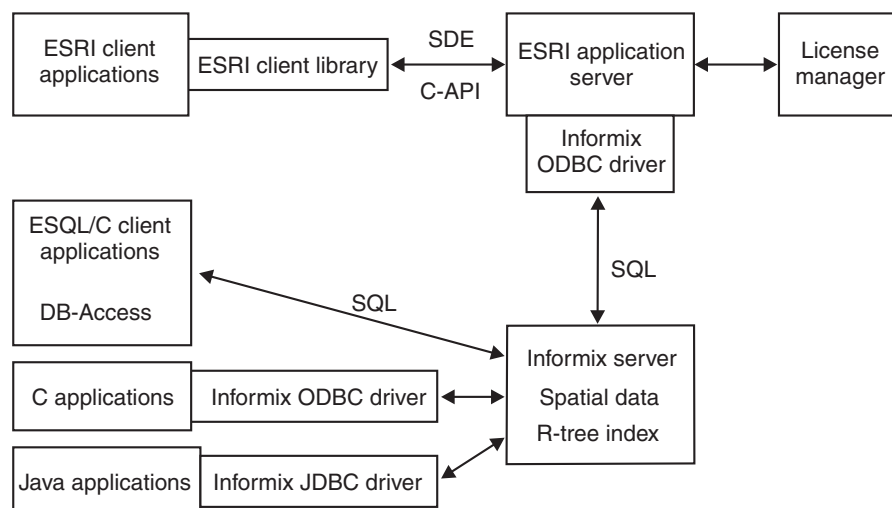

Figure 1-2. Architecture for IBM Informix and spatial applications

For each spatial data type, there is a text file import and a text file export routine. Whenever you execute a load or unload statement in the DB-Access utility, these import and export routines are automatically called (the **dbimport** and **dbexport** utilities also use these routines).

The ESRI ArcSDE service provides immediate access to the spatial data stored in your IBM Informix database for the powerful ESRI GIS software programs: ArcView GIS, MapObjects, and ArcInfo software. The ArcSDE service automatically converts spatial column data into ESRI shape representation, making it available to all ESRI-supported applications and other applications capable of reading this format. Accessing spatially enabled tables through the ArcSDE service allows you to write applications using the existing tools offered by ESRI GIS software or create applications using the SDE C application programming interface (API). An experienced open database connectivity (ODBC) programmer can also make calls to the IBM Informix Spatial DataBlade Module SQL functions.

You can use DB-Access to run SQL queries against your spatial data. You can also write applications that access the database:

- **ESQL/C applications.** Use the IBM Informix Client Software Development Kit (Client SDK), Version 2.5 or later, to connect to the IBM Informix server.
- **C applications.** Use the IBM Informix ODBC Driver to connect to the IBM Informix server.
- **Java applications.** Use the IBM Informix JDBC Driver to connect to the IBM Informix server.

Querying the spatial columns directly requires converting the data to one of the three supported external formats. The **ST_AsText()** function converts a spatial column value to the OGC Well-Known Text (WKT) representation. The **ST_AsBinary()** and **SE_AsShape()** functions convert the spatial column values to OGC Well-Known Binary (WKB) and ESRI shape formats. Once converted, applications can display or manipulate the data.

You use an R-tree index to allow indexing of spatial data. R-tree indexes are specifically designed to provide fast, efficient access to spatial data.

You can find FAQs, examples, tips, documentation, tuning information for using spatial data at <http://www.ibm.com/software/data/informix/blades/spatial/>.

Preparing to use spatial data

Before you can create a spatial table, you must prepare the database server.

To prepare the database server for spatial data:

1. Set the **STACKSIZE** configuration parameter in the **onconfig** file to 64. Increasing the stack size prevents stack overflow errors.
2. If necessary, create a default sbspace and set the **SBSPACENAME** configuration parameter in the **onconfig** file. If you do not have a default sbspace when you

create spatial tables, the database server creates one in the root dbspace and dynamically sets the SBSPACENAME configuration parameter.

3. If necessary, create the system sbspace and set the SYSSBSPACENAME configuration parameter in the onconfig file. The value of the SYSSBSPACENAME configuration parameter can be the same as the value of the SBSPACENAME configuration parameter. If you do not have a system sbspace when you create spatial tables, the database server creates one in the root dbspace and dynamically sets the SYSSBSPACENAME configuration parameter.
4. Restart the database server to enable the changes to the onconfig file.

[➡ SBSPACENAME configuration parameter \(Administrator's Reference\)](#)

[➡ STACKSIZE configuration parameter \(Administrator's Reference\)](#)

Sbspaces for spatial data

Spatial tables require sbspaces to store spatial data and statistics about spatial tables.

Spatial data is stored in the default sbspace when a geometry exceeds 930 bytes, for example, a line or polygon with more than 50 vertices. The default sbspace is specified by the SBSPACENAME configuration parameter in the onconfig file. If you want to store spatial data in a different sbspace, use the PUT clause in the CREATE TABLE statement to specify a different sbspace when you create your spatial tables.

If you do not create a default sbspace or specify a different sbspace when you create a spatial table, the database server creates the default sbspace in the root dbspace for the database server. To avoid filling up your root dbspace, create the default sbspace on a different disk.

When you create an sbspace for spatial data, you can enable the logging of user data. By default, only smart large object metadata is logged and smart large object user data is not logged. Therefore, only the metadata can be restored, and the user data cannot be restored. If you create the spatial data sbspace with logging, you can backup and restore the user data as well as the metadata. You can create a logged sbspace by using the **-DF "LOGGING=ON"** option of the **onspaces** utility.

You can move the smart large object containing metadata about spatial data to a different sbspace by running the ALTER TABLE statement with the PUT clause to specify a different sbspace for the **SE_MetadataTable** table and then running the **SE_MetadataInit()** function. For example, the following statements put the metadata table in an sbspace named **mysbspace**:

```
ALTER TABLE SE_MetadataTable PUT smd IN (mysbspace);  
EXECUTE FUNCTION SE_MetadataInit();
```

When the UPDATE STATISTICS MEDIUM or HIGH statements are run on spatial tables, the database server stores the statistics in the sbspace specified by the SYSSBSPACENAME configuration parameter in the onconfig file.

The spatial_references table

The **spatial_references** table stores data about each map projection that you use to store the spherical geometry of the Earth. For example, your data may use the Mercator projection. The **spatial_references** table holds information to translate the spatial data into a flat, X-Y coordinate system.

You must set up appropriate entries for your spatial data in the **spatial_references** table.

The mapping between spheroidal and flat data is called a *spatial reference system*. The spatial reference ID (SRID) is the unique key for the record in the **spatial_references** table describing a particular spatial reference system. All spatial reference systems that you use in your database must have a record in the **spatial_references** table. All geometries in a spatial column must use the same spatial reference system. (*Geometry* is the term adopted by the OpenGIS Consortium to refer to two-dimensional spatial data).

The IBM Informix spatial functions use the parameters of a spatial reference system to translate and scale each floating point coordinate of the geometry into 54-bit positive integers prior to storage. When retrieved, the coordinates are restored to their external floating point format.

Related concepts:

- “Overview of using spatial data” on page 1-2

The structure of the spatial_references table

Before you can create geometry and insert it into a table you must enter the SRID of that geometry into the **spatial_references** table.

The columns of the **spatial_references** table are described in the following table.

Table 1-1. The spatial_references table

Column name	Type	Example value	Description
srid	INTEGER NOT NULL	12345	Primary key: the unique key for the record describing a particular spatial reference system
description	VARCHAR(64)	WGS 1984	A text description of the spatial reference system
auth_name	VARCHAR(255)	EPSG	The name of the standard or standards body cited for the reference system
auth_srid	INTEGER	4326	The ID of the spatial reference system as defined by the authority cited in auth_name

Table 1-1. The `spatial_references` table (continued)

Column name	Type	Example value	Description
falsex	FLOAT NOT NULL	-180	The external floating point X coordinates are converted to integers for storage in the database by subtracting the falsex values.
falsey	FLOAT NOT NULL	-90	The external floating point Y coordinates are converted to integers for storage in the database by subtracting the falsey values.
xyunits	FLOAT NOT NULL	1000000	Before being inserted into the database, the external floating point X and Y coordinates are scaled by the value in xyunits , adding a half unit, and truncating the remainder.
falsez	FLOAT NOT NULL	-1000	The external floating point Z coordinates are converted to integers for storage in the database by subtracting the falsez values.
zunits	FLOAT NOT NULL	1000	A factor used to scale the Z-coordinate
falsem	FLOAT NOT NULL	-1000	The external floating point M coordinates are converted to integers for storage in the database by subtracting the falsem values.
munits	FLOAT NOT NULL	1000	A factor used to scale the measure values
srttext	CHAR(2048)	GEOGCS["GCS_WGS_1984", DATUM["D_WGS_1984", SPHEROID["WGS_1984", 6378137, 298.257223563]], PRIMEM["Greenwich",0], UNIT["Degree", 0.0174532925199433]]	The srttext column contains the WKT representation of the spatial reference system. Appendix B, "OGC well-known text representation of spatial reference systems," on page B-1, contains a complete description of this format.

The following example shows how to insert a spatial reference system into the `spatial_references` table:

```
INSERT INTO spatial_references
(srid, description, auth_name, auth_srid, falsex, falsey,
 xyunits, falsez, zunits, falsem, munits, srttext)
VALUES (1, NULL, NULL, NULL, 0, 0, 100, 0, 1, 0, 1, 'UNKNOWN');
```

In this example, the spatial reference system has an SRID value of 1, a false X, Y of (0,0), and its system units are 100. The Z coordinate and measure offsets are 0, while the Z coordinate and measure units are 1.

The next topics describe how to choose appropriate values for the **falsex**, **falsey**, **falsez**, **falsem**, **xyunits**, **zunits**, and **munits** columns.

Select a false origin and system units

Select a false origin and system unit to store all of your coordinate values at an acceptable scale. To do so, you must know the range of your data and the scale to maintain. Because coordinates are stored as positive 54-bit integers, the maximum

range of values allowed is between 0 and 9,007,199,254,740,991, but the actual range is dependent on the false origin and system units of the spatial reference system.

A negative false origin shifts the range of values in the negative direction. A positive false origin shifts the range of values in the positive direction. For example, a false origin of -1000, with a system unit of one, stores a range of values between -1000 to $2^{53} - 1000$.

The system unit scales the data and cannot be less than one. The larger the system unit the greater the scale that can be stored, but the smaller the range of values. For example, given a system unit of 1000 and a false origin of zero, data with three digits to the right of the decimal point are supported; the range of possible values is reduced to 0.001 to 2^{50} .

If you want to maintain a scale of three digits to the right of the decimal point, set your system units to 1,000. Set the false origin to less than the minimum coordinate value in your data set. The false origin must be small enough to account for any buffering of the data. If the minimum coordinate value is -10,000 and your application includes functions that buffer the data by 5,000, the false origin must be at least -15,000. Finally, make sure that the maximum ordinate value is not greater than 2^{53} by applying the following formula to the maximum value. This formula converts floating point coordinates into system units:
stored value = truncate(((ordinate - false origin) * system unit) + 0.5)

“The SE_CreateSRID() function” on page 8-25 describes the **SE_CreateSRID()** utility function that, given the X and Y extents of a spatial data set, computes the false origin and system units.

Restriction: Do not change a spatial reference system's false origin and system units after you have inserted spatial data into a table using that SRID. These parameters translate and scale your data prior to storage. If you change these values, you will be unable to retrieve your original floating point coordinate data.

“The SE_CreateSRID() function” on page 8-25

Work with spatial tables

These topics describe how to create tables with spatial columns, how to insert and update spatial data, and how to create indexes on spatial columns.

Related concepts:

“Overview of using spatial data” on page 1-2

Create a spatial table

A *spatial table* is a table that includes one or more spatial columns. To create a spatial table, include a spatial column in the column clause of the CREATE TABLE statement.

You should create your spatial tables in a logged database.

A spatial column can only accept data of the type required by the spatial column. For example, a column of ST_Polygon type rejects integers, characters, and even other types of geometry. In addition to the geometry column, ESRI client software also requires a unique key, the **se_row_id** INTEGER column.

Consider the sensitive areas and hazardous waste sites example. Stored in the **sensitive_areas** table are schools, hospitals, and playgrounds, while the **hazardous_sites** table holds locations of hazardous waste sites. The ST_Polygon data type is used to store the sensitive areas, while hazardous sites are stored as points using the ST_Point type:

```
CREATE TABLE sensitive_areas (se_row_id integer NOT NULL,
                             area_id integer,
                             name varchar(128),
                             size float,
                             type varchar(10),
                             zone ST_Polygon);

CREATE TABLE hazardous_sites (se_row_id integer NOT NULL,
                               site_id integer,
                               name varchar(40),
                               location ST_Point);
```

Establish a spatial reference system

Before you populate a spatial table, you must define a spatial reference system for all of the geometry data that will be loaded into a spatial column.

Spatial reference system information is stored in the **spatial_references** table. The SRID of a geometry's spatial reference system is stored with the geometry itself, so it is important that you choose an SRID carefully.

If the coordinates of your data are in latitude and longitude, you might be able to use one of several predefined SRIDs that are inserted into the **spatial_references** table. If the coordinates are in a different system (for example, UTM) you must define a new spatial reference system.

Tip: If your spatial data is supplied in shapefiles, you can use the **infoshp** utility to help you define a spatial reference system. The **SE_CreateSRID()** and **SE_CreateSrtxt()** SQL functions (described in Chapter 8, "Spatial functions," on page 8-1) can also be helpful.

For the hazardous sites and sensitive areas example, the coordinates are in a local countywide XY coordinate system, so we must create a new spatial reference system. The X and Y coordinates range from 0 to 250000. The **SE_CreateSRID()** function performs the calculation:

```
EXECUTE FUNCTION SE_CreateSRID(0, 0, 250000, 250000,
                               "Springfield county XY coord system");
```

(expression)

5

The return value of the function is the SRID, which can then be used when inserting data.

Related concepts:

"The spatial_references table" on page 1-5

The geometry_columns table

When you create a table with a spatial column, or add a spatial column to an existing table, ESRI client software also requires you to add an entry to the **geometry_columns** table. The **geometry_columns** table is a metadata table, like **spatial_references**, that stores data about data.

For the hazardous sites and sensitive areas example, the INSERT statements look like this:

```
INSERT INTO geometry_columns
    (f_table_catalog, f_table_schema, f_table_name,
     f_geometry_column, geometry_type, srid)
VALUES ("mydatabase",      -- database name
        "ralph",          -- user name
        "sensitive_areas", -- table name
        "zone",           -- spatial column name
        5,                -- column type (5 = polygon)
        5);              -- srid
```

```
INSERT INTO geometry_columns
    (f_table_catalog, f_table_schema, f_table_name,
     f_geometry_column, geometry_type, srid)
VALUES ("mydatabase",      -- database name
        "ralph",          -- user name
        "hazardous_sites", -- table name
        "location",       -- spatial column name
        1,                -- column type (1 = point)
        5);              -- srid
```

Appendix F, “Values for the geometry_type column,” on page F-1, shows valid entries for the **geometry_type** column and the shapes they represent.

Tip: The **loadshp** utility, described in Appendix A, “Load and unload shapefile data,” on page A-1, automatically creates these entries in the **geometry_columns** table. The ESRI **shp2sde** command also does this.

Insert data into a spatial column

You can copy data into or out of the database using the traditional external geometry formats or latitude and longitude-based geometry formats.

These geometry formats include:

- IBM Informix load format
- OGC well-known text representation (WKT)
- OGC well-known binary representation (WKB)
- ESRI shapefile format
- Geography Markup Language (GML)
- Keyhole Markup Language (KML)

Except for the IBM Informix load format, all of these formats require the use of input and output conversion functions to insert spatial data into, and retrieve data from, a database. You use spatial data type functions to convert data into its stored data types for each of these formats.

For example, in the SQL statements below, records are inserted into the **sensitive_areas** and **hazardous_sites** table. The **ST_PolyFromText()** function converts the well-known text representation of a polygon into an ST_Polygon type before inserting it into the **ZONE** column of the **sensitive_areas** table. Likewise, the **ST_PointFromText()** function converts the well-known text representation of a point into an ST_Point type before inserting it into the **LOCATION** column of the **hazardous_sites** table. You can also enter data in ESRI shapefile format using the **SE_PolyFromShape()** and **ST_PointFromShape()** functions, or in well-known binary format using the **ST_PolyFromWKB()** and **ST_PointFromWKB()** functions.

```

INSERT INTO sensitive_areas VALUES (
    1, 408, 'Summerhill Elementary School', 67920.64, 'school',
    ST_PolyFromText('polygon ((52000 28000,58000 28000,58000 23000,
52000 23000,52000 28000))',5)
);

```

```

INSERT INTO hazardous_sites VALUES (
    1, 102, 'W. H. Kleenare Chemical Repository',
    ST_PointFromText('point (17000 57000)',5)
);

```

Alternatively, you can use the IBM Informix load format, in which case a conversion function is not required:

```

INSERT INTO sensitive_areas VALUES (
    2, 129, 'Johnson County Hospital', 102281.91, 'hospital',
    '5 polygon ((32000 55000,32000 68000,38000 68000,38000 52000,
35000 52000,35000 55000,32000 55000))'
);

```

```

INSERT INTO hazardous_sites VALUES (
    2, 59, 'Landmark Industrial',
    '5 point (58000 49000)'
);

```

In the simple example above, a few records are inserted into database tables. However, the actual amount of data loaded into a GIS system usually ranges between ten thousand records for smaller systems and one hundred million records for larger systems. The IBM Informix database server can handle the entire range.

Loading methods

You have several options for loading data. If you are performing a bulk load of data, you can avoid large numbers of log records by temporarily turning off logging for the database until the data is loaded.

One option for loading data is to use the **loadshp** utility. This utility allows you to copy data from ESRI shapefiles to an IBM Informix database. A companion utility, **unloadshp**, allows you to unload data from a database to shapefiles.

Important: The **loadshp** utility does not add information to ESRI system tables, such as the **layers** table. Therefore, data loaded with the **loadshp** utility is not accessible to ArcSDE and other ESRI client tools. Use the ESRI **shp2sde** command to load data if you want to access it using ESRI client tools. Data loaded using the **loadshp** utility is accessible to client programs that do not depend on ESRI system tables other than the OGC-standard **geometry_columns** and **spatial_references** tables.

Another option is to develop your own loader application. The source code for two sample programs, **load_wkb** and **load_shapes**, is supplied with the IBM Informix software. These programs illustrate how to convert data into OGC well-known binary and ESRI shapefile formats. The programs can be modified and linked into existing applications. They are located under the `$INFORMIXDIR/extend/spatial.version/examples` directory. ESQL/C and ODBC versions of both programs are provided.

Alternatively, you can acquire data from a vendor and load the data through the ESRI SDE server. The **shp2sde** command loads shapefiles into an existing table. Accessing spatial tables through SDE software also provides immediate access to

SDE client software such as ArcView GIS, MapObjects, ARC/INFO and ArcExplorer. MicroStation and AutoCAD are also accessible through SDE CAD client software.

Related reference:

Appendix A, “Load and unload shapefile data,” on page A-1
Chapter 3, “Data exchange formats,” on page 3-1

Create a spatial index

Since spatial columns contain multidimensional geographic data, applications querying those columns require an index strategy that quickly identifies all geometries that satisfy a specified spatial relationship. For this reason the IBM Informix database server provides support for building a spatial index, called the *R-tree index*.

The two-dimensional R-tree index differs from the traditional hierarchical (one-dimensional) B-tree index. Spatial data is two-dimensional, so you cannot use the B-tree index for spatial data. Similarly, you cannot use an R-tree index with non-spatial data.

To create an R-tree index on the **location** column of the **hazardous_sites** table in our example, use the CREATE INDEX statement:

```
CREATE INDEX location_ix
  ON hazardous_sites (location ST_Geometry_ops)
  USING RTREE;
```

Tip: The **loadshp** utility automatically creates an R-tree index for you after loading data. The ESRI **shp2sde** command can also be used to create an R-tree index.

Restriction: You cannot rename a database if the database contains a table that has an R-tree index defined on it, because R-tree indexes are implemented with secondary access method. Databases that use primary access method (also called virtual table interface) or secondary access method (also called virtual index interface) cannot be renamed.

The query optimizer does not use the R-tree index unless the statistics on the table are up-to-date. If the R-tree index is created after the data has been loaded, the statistics are current and the optimizer will use the index. However, if the index is created before the data is loaded, the optimizer will not use the R-tree index, because the statistics are out of date. To update statistics, use the UPDATE STATISTICS SQL statement:

```
UPDATE STATISTICS FOR TABLE hazardous_sites;
```

Related reference:

Appendix A, “Load and unload shapefile data,” on page A-1

Update values in a spatial column

The SQL UPDATE statement alters the values in a spatial column just as it does any other type of column. Typically, spatial column data must be retrieved from the table, altered in a client application, and then returned to the server.

The following pair of SQL statements illustrates how to fetch the spatial data from one row in the **hazardous_sites** table and then update the same item:

```

SELECT ST_AsText(location) FROM hazardous_sites
WHERE site_id = 102;

UPDATE hazardous_sites
SET location = ST_PointFromText('point(18000 57000)', 5)
WHERE site_id = 102;

```

Perform spatial queries

A common task in a GIS application is to retrieve the visible subset of spatial data for display in a window. The easiest way to do this is to define a polygon representing the boundary of the window and then use the **SE_EnvelopesIntersect()** function to find all spatial objects that overlap this window.

For example:

```

SELECT name, type, zone FROM sensitive_areas
WHERE SE_EnvelopesIntersect(zone,
    ST_PolyFromText('polygon((20000 20000,60000 20000,
60000 60000,20000 60000,20000 20000))', 5));

```

Queries can also use spatial columns in the SQL WHERE clause to qualify the result set; the spatial column does not need to be in the result set at all. For example, the following SQL statement retrieves each sensitive area with its nearby hazardous waste site if the sensitive area is within five miles of a hazardous site. The **ST_Buffer()** function generates a circular polygon representing the five-mile radius around each hazardous location. The **ST_Polygon** geometry returned by the **ST_Buffer()** function becomes the argument of the **ST_Overlaps()** function, which returns t (TRUE) if the **zone** **ST_Polygon** of the **sensitive_areas** table overlaps the **ST_Polygon** generated by the **ST_Buffer()** function:

```

SELECT sa.name sensitive_area, hs.name hazardous_site
FROM sensitive_areas sa, hazardous_sites hs
WHERE ST_Overlaps(sa.zone, ST_Buffer(hs.location, 26400));

```

```

sensitive_area Summerhill Elementary School
hazardous_site Landmark Industrial

```

```

sensitive_area Johnson County Hospital
hazardous_site Landmark Industrial

```

Related reference:

Chapter 5, “Run parallel queries,” on page 5-1

Optimize spatial queries

You can set environment variables to optimize your spatial queries.

Running **UPDATE STATISTICS HIGH** on a very large table might require large amounts of shared memory (tens of megabytes). If sufficient shared memory is unavailable, **UPDATE STATISTICS** will fail. If it fails, you can use the **ST_MAXLEVELS** environment variable to reduce the memory requirements. The default value is 16. Decrease it to reduce the amount of memory that is needed to build a histogram. Decreasing the value of **ST_MAXLEVELS** might result in a less accurate histogram than would otherwise be possible. The minimum recommended value is 12.

Set the **ST_COSTMULTIPLIER** environment variable to a non-zero positive value to adjust the cost for each row that is computed by the database server. The database server multiplies its cost estimate by this value.

If you set either of these environment variables, you must stop and restart the database server for the change to take effect.

To improve performance, the database server uses a pool of temporary memory buffers for processing spatial data. You can change the behavior of this memory management system, if necessary, in two ways:

- By setting the **ST_MEMMODE** environment variable.
- By changing the value of the MemMode user-settable parameter.

The **ST_MEMMODE** environment variable can have three values:

- 0 Disables memory buffer reuse. Temporary buffers, used for processing spatial data, are allocated from the `per_routine` memory pool and are not reused between UDR invocations. Several memory buffers are typically allocated and freed for every row in a table that is being processed.
- 1 Enables memory buffer reuse. This is the default value. Temporary buffers are allocated from the `per_command` memory pool. As they are freed, they are returned to a pool and are reused for subsequent memory requests. This pool is drained when the UDR sequence completes, which is after all rows in a table are processed.
- 2 Disables memory buffer reuse, but allocate all temporary buffers from the server `per_command` memory pool. This mode, in conjunction with the **DONTDRAINPOOLS** server environment variable, has an effect similar to `mode=1`, but lets the server manage the memory.

Buffers that hold UDR return values are allocated from the `per_command` memory pool and are reused between UDR invocations. The **ST_MEMMODE** environment variable must be set before the server starts. If you change the value of the environment variable, you must restart the server. To override an existing value without restarting the server, you can also change the value of a parameter called MemMode.

MemMode is a parameter that takes the same values as the **ST_MEMMODE** environment variable. Unlike the environment variable, you can set the value of MemMode at any time using the **SE_ParamSet()** function as described in “The **SE_ParamSet()** function” on page 8-89. The value of MemMode takes precedence over the value of the **ST_MEMMODE** environment variable. MemMode remains set until the server is shut down. When the server is restarted, it sets the value to that of **ST_MEMMODE**.

Use the following functions to view and change the value of the MemMode parameter:

- **SE_ParamGet()**
- **SE_ParamSet()**

Related reference:

“The **SE_ParamGet()** function” on page 8-88

“The **SE_ParamSet()** function” on page 8-89

Spatial data replication

You can use spatial data types with Enterprise Replication and high-availability clusters.

The following conditions must be met to replicate spatial data:

- You must ensure that all copies of the **spatial_references** table are synchronized at all times.
- Spatial data type columns in tables that you include in your data replication system must be nullable.

For information about Enterprise Replication, see the *IBM Informix Enterprise Replication Guide*. For information about high-availability clusters, see the *IBM Informix Administrator's Guide*.

The IBM Informix Web Feature Service

The IBM Informix Web Feature Service (WFS) is a transaction service that acts as a presentation layer for spatial data.

WFS supports the following operations:

- Creating new feature instances
- Deleting feature instances
- Updating feature instances
- Querying features based on spatial and non-spatial constraints

The IBM Informix WFS includes a CGI client program and an IBM Informix server-side function to let web programs send requests to IBM Informix for geographical features. These geographical features are encoded in the platform-independent, XML-based geography markup language (GML). You can use WFS with the IBM Informix spatial data types or the Geodetic DataBlade module to enable IBM Informix database servers to manage geographical features. WFS is written to the Open Geospatial Consortium (OGC) standard in document 04-094, Web Feature Service Implementation Specification Version 1.1.0. For more information, see the *IBM Informix Database Extensions User's Guide* and the OGC website at <http://www.opengeospatial.org>.

Chapter 2. Spatial data types

IBM Informix spatial data types are divided into two categories: the base geometry subclasses and the homogeneous collection subclasses.

- The base geometries are:
 - ST_Point
 - ST_LineString
 - ST_Polygon
- The homogeneous collections are:
 - ST_MultiPoint
 - ST_MultiLineString
 - ST_MultiPolygon

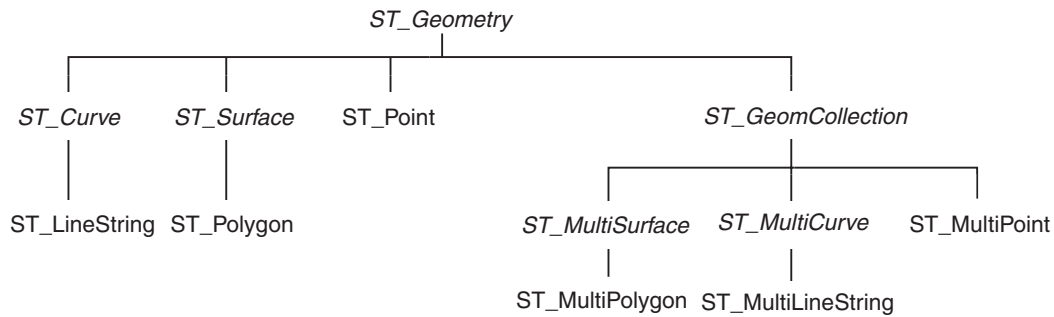

Homogeneous collections are collections of base geometries; in addition to sharing base geometry properties, homogeneous collections also have some properties of their own.

The **ST_GeometryType()** function takes an ST_Geometry and returns the instantiable subclass in the form of a character string. The **ST_NumGeometries()** function takes a homogeneous collection and returns the number of base geometry elements it contains. The **ST_GeometryN()** function takes a homogeneous collection and an index and returns the *n*th base geometry.

Properties of spatial data types

The OGC, in its publication of *OpenGIS Features for ODBC (SQL) Implementation Specification*, selected the term *geometry* to represent spatial features such as point locations and polygons. Typically, points represent an object at a single location, linestrings represent a linear characteristic, and polygons represent a spatial extent. An abstract definition of the OpenGIS noun *geometry* might be, “a point or aggregate of points symbolizing a feature on the ground.”

The ST_Geometry data type is an abstract noninstantiable superclass. Its subclasses provide instantiable data types. This means you can define table columns to be of such types. The following figure shows the class hierarchy for the IBM Informix spatial data types.

italics represent a noninstantiable class

Figure 2-1. Data types class diagram

Throughout the remainder of this publication, the terms *geometry* or *geometries* collectively refer to the superclass `ST_Geometry` data type and all of its subclass data types. Whenever it is necessary to specify the geometry superclass directly, it will be referred to as the `ST_Geometry` superclass or the `ST_Geometry` data type.

Tip: You can define a column as type `ST_Geometry`, but `ST_Geometry` values cannot be inserted into it since they cannot be instantiated. However, any of the `ST_Geometry` subclass data type values can be inserted into this column.

The rest of this section describes the properties of the spatial data types. Each subclass data type inherits the properties of the `ST_Geometry` superclass and adds properties of its own. Functions that operate on the `ST_Geometry` data type also operate on any of the subclass data types. However, functions that are defined at the subclass level only operate on that data type and its subclasses data types.

Interior, boundary, and exterior

All geometries occupy a position in space defined by their interior, boundary, and exterior.

Exterior

All space not occupied by the geometry.

Boundary

Serves as the interface between its interior and exterior.

Interior

The space occupied by the geometry.

The subclass inherits the interior and exterior properties from `ST_Geometry`; the boundary property differs for each data type.

The `ST_Boundary()` function takes an `ST_Geometry` type and returns an `ST_Geometry` that represents the source `ST_Geometry` boundary.

Simple or nonsimple

Some subclasses of `ST_Geometry` (`ST_LineStrings`, `ST_MultiPoints`, and `ST_MultiLineStrings`) are either simple or nonsimple.

They are simple if they obey all topological rules imposed on the subclass and nonsimple if they bend a few rules.

- `ST_LineString` is simple if it does not intersect its interior.

- `ST_MultiPoint` is simple if none of its elements occupy the same coordinate space.
- `ST_MultiLineString` is simple if none of its element's interiors intersect.

The `ST_IsSimple()` function takes an `ST_Geometry` and returns `t` (TRUE) if the `ST_Geometry` is simple and `f` (FALSE), otherwise.

Empty or not empty

A geometry is empty if it does not have any points.

An empty geometry has a NULL envelope, boundary, interior, and exterior. An empty geometry is always simple and can have Z coordinates or measures. Empty linestrings and multilinestrings have a 0 length. Empty polygons and multipolygons have 0 area.

The `ST_IsEmpty()` function takes an `ST_Geometry` and returns `t` (TRUE) if the `ST_Geometry` is empty and `f` (FALSE) otherwise.

Number of points

A geometry can have zero or more points.

A geometry is considered empty if it has zero points. The `ST_Point` subclass is the only geometry that is restricted to zero or one point; all other subclasses can have zero or more.

Envelope

The envelope of a geometry is the bounding geometry formed by the minimum and maximum (X,Y) coordinates.

The envelopes of most geometries form a boundary rectangle; however, the envelope of a point is the point itself, since its minimum and maximum coordinates are the same, and the envelope of a horizontal or vertical linestring is a linestring represented by the endpoints of the source linestring.

The `ST_Envelope()` function takes an `ST_Geometry` and returns a `ST_Geometry` that represents the source `ST_Geometry` envelope.

Dimension

A geometry can have a dimension of 0, 1, or 2.

- 0 The geometry has neither length or area.
- 1 The geometry has a length.
- 2 The geometry contains area.

The point and multipoint subclasses have a dimension of 0. Points represent zero-dimensional features that can be modeled with a single coordinate, while multipoints represent data that must be modeled as a cluster of unconnected coordinates.

The subclasses linestring and multilinestring have a dimension of 1. They store road segments, branching river systems, and any other features that are linear in nature.

Polygon and multipolygon subclasses have a dimension of 2. Forest stands, parcels, water bodies, and other features whose perimeter encloses a definable area can be rendered by either the polygon or multipolygon data type.

Dimension is important not only as a property of the subclass, but also plays a part in determining the spatial relationship of two features. The dimension of the resulting feature or features determines whether the operation was successful. The dimension of the features is examined to determine how they should be compared.

The **ST_Dimension()** function takes an ST_Geometry and returns its dimension as an integer.

Z coordinates

Some geometries have an associated altitude or depth.

Each of the points that form the geometry of a feature can include an optional Z coordinate that represents an altitude or depth normal to the earth's surface.

The **SE_Is3D()** predicate function takes an ST_Geometry and returns t (TRUE) if the function has Z coordinates and f (FALSE), otherwise.

Measures

Measures are values assigned to each coordinate.

The value represents anything that can be stored as a double-precision number.

The **SE_IsMeasured()** function takes an ST_Geometry and returns t (TRUE) if it contains measures and f (FALSE), otherwise.

Spatial reference system

The spatial reference system identifies the coordinate transformation matrix for each geometry.

All spatial reference systems known to the database are stored in the **spatial_references** table.

The **ST_SRID()** function takes an ST_Geometry and returns its spatial reference identifier as an integer.

Related concepts:

“The spatial_references table” on page 1-5

ST_Point data type

The ST_Point data type is a zero-dimensional geometry that occupies a single location in coordinate space. ST_Point is used to define features such as oil wells, landmarks, and elevations.

Properties

An ST_Point has a single X,Y coordinate value, is always simple, and has a NULL boundary. An ST_Point may include a Z coordinate and an M value.

Functions

The following functions operate solely on the `ST_Point` data type:

`ST_X()`

The function returns a point data type's X coordinate value as a double-precision number.

`ST_Y()`

The function returns a point data type's Y coordinate value as a double-precision number.

`SE_Z()`

The function returns a point data type's Z coordinate value as a double-precision number.

`SE_M()`

The function returns a point data type's M coordinate value as a double-precision number.

ST_LineString data type

The `ST_LineString` data type is a one-dimensional object stored as a sequence of points defining a linear interpolated path. `ST_LineString` types are often used to define linear features such as roads, rivers, and power lines.

Properties

An `ST_LineString` is simple if it does not intersect its interior. The endpoints (the boundary) of a closed `ST_LineString` occupy the same point in space. An `ST_LineString` is a ring if it is both closed and simple. In addition to properties inherited from the superclass `ST_Geometry`, `ST_LineString` values have length.

The endpoints normally form the boundary of a `ST_LineString` unless the `ST_LineString` is closed, in which case the boundary is `NULL`. The interior of a `ST_LineString` is the connected path that lies between the endpoints, unless it is closed, in which case the interior is continuous. The following figure shows examples of `ST_LineString` objects: (1) is a simple nonclosed `ST_LineString`; (2) is a nonsimple nonclosed `ST_LineString`; (3) is a closed simple `ST_LineString` and therefore is a ring; (4) is a closed nonsimple `ST_LineString`—it is not a ring.

Figure 2-2. Examples of `ST_LineString` objects

Functions

The following functions operate on `ST_LineString`:

`ST_StartPoint()`

The function returns the linestring's first point.

ST_EndPoint()

The function returns the linestring's last point.

ST_PointN()

The function takes an ST_LineString and an index to *n*th point and returns that point.

ST_Length()

The function returns the linestring's length as a double-precision number.

ST_NumPoints()

The function returns the number of points in the linestring's sequence as an integer.

ST_IsRing()

The function returns t (TRUE) if the ST_LineString is a ring and f (FALSE) otherwise.

ST_IsClosed()

The function returns t (TRUE) if the ST_LineString is closed and f (FALSE) otherwise.

ST_Polygon()

The function creates a polygon from an ST_LineString that is a ring.

ST_Polygon data type

The ST_Polygon data type is a two-dimensional surface stored as a sequence of points defining its exterior bounding ring and 0 or more interior rings. Most often, ST_Polygon defines parcels of land, water bodies, and other features having spatial extent.

Properties

The ST_Polygon is always simple. The exterior and any interior rings define the boundary of an ST_Polygon, and the space enclosed between the rings defines the interior of ST_Polygon. The rings of an ST_Polygon can intersect at a tangent point, but never cross. In addition to the other properties inherited from the superclass, ST_Geometry, ST_Polygon has area.

The following figure shows examples of ST_Polygon objects: (1) is an ST_Polygon whose boundary is defined by an exterior ring; (2) is an ST_Polygon whose boundary is defined by an exterior ring and two interior rings. The area inside the interior rings is part of the ST_Polygon's exterior; (3) is a legal ST_Polygon because the rings intersect at a single tangent point.

Figure 2-3. Examples of ST_Polygon objects

Functions

The following functions operate on ST_Polygon:

ST_Area()

The function returns the polygon's area as a double-precision number.

ST_ExteriorRing()

The function returns the polygon's exterior ring as an ST_LineString.

ST_NumInteriorRing()

The function returns the number of interior rings that the polygon contains.

ST_InteriorRingN()

The function takes an ST_Polygon and an index and returns the *n*th interior ring as an ST_LineString.

ST_Centroid()

The function returns an ST_Point that is the center of the ST_Polygon's envelope.

ST_PointOnSurface()

The function returns an ST_Point that is guaranteed to be on the surface of the ST_Polygon.

ST_Perimeter()

The function returns the perimeter of an ST_Polygon or ST_MultiPolygon.

ST_MultiPoint data type

The ST_MultiPoint data type is a collection of ST_Points. ST_MultiPoint can define aerial broadcast patterns and incidents of a disease outbreak.

An ST_MultiPoint is simple if none of its elements occupy the same coordinate space. Just like its elements, it has a dimension of 0. The boundary of a ST_MultiPoint is NULL.

ST_MultiLineString data type

The ST_MultiLineString data type is a collection of ST_LineStrings. ST_MultiLineStrings are used to define streams or road networks.

Properties

ST_MultiLineStrings are simple if they only intersect at the endpoints of the ST_LineString elements. ST_MultiLineStrings are nonsimple if the interiors of the ST_LineString elements intersect.

The boundary of an ST_MultiLineString is the non-intersected endpoints of the ST_LineString elements. The ST_MultiLineString is closed if all its ST_LineString elements are closed. The boundary of a ST_MultiLineString is NULL if all the endpoints of all the elements are intersected. In addition to the other properties inherited from the superclass ST_Geometry, ST_MultiLineStrings have length.

The following figure shows examples of ST_MultiLineStrings:

- (1) is a simple ST_MultiLineString whose boundary is the four endpoints of its two ST_LineString elements.
- (2) is a simple ST_MultiLineString because only the endpoints of the ST_LineString elements intersect. The boundary is two non-intersected endpoints.

- (3) is a non-simple ST_MultiLineString because the interior of one of its ST_LineString elements is intersected. The boundary of this ST_MultiLineString is the three non-intersected endpoints.
- (4) is a simple non-closed ST_MultiLineString. It is not closed because its element ST_LineStrings are not closed. It is simple because none of the interiors of any of the element ST_LineStrings intersect.
- (5) is a simple closed ST_MultiLineString. It is closed because all its elements are closed. It is simple because none of its elements intersect at the interiors.

Figure 2-4. Examples of ST_MultiLineString objects

Functions

The following functions operate on ST_MultiLineStrings:

ST_Length()

The function returns the cumulative length of all its ST_LineString elements as a double-precision number.

ST_IsClosed()

The function returns t (TRUE) if the ST_MultiLineString is closed and f (FALSE), otherwise.

ST_MultiPolygon data type

The ST_MultiPolygon data type defines features such as a forest stratum or a non-contiguous parcel of land such as an island chain.

Properties

The boundary of an ST_MultiPolygon is the cumulative length of its elements' exterior and interior rings. The interior of an ST_MultiPolygon is defined as the cumulative interiors of its element ST_Polygons. The boundary of an ST_MultiPolygon's elements can only intersect at a tangent point. In addition to the other properties inherited from the superclass ST_Geometry, ST_MultiPolygons have area.

The following figure shows examples of ST_MultiPolygon: (1) is ST_MultiPolygon with two ST_Polygon elements. The boundary is defined by the two exterior rings

and the three interior rings; (2) is an `ST_MultiPolygon` with two `ST_Polygon` elements. The boundary is defined by the two exterior rings and the two interior rings. The two `ST_Polygon` elements intersect at a tangent point.

Figure 2-5. Examples of `ST_MultiPolygon` objects

Functions

The following functions that operate on `ST_MultiPolygons`:

`ST_Area()`

The function returns the cumulative area of its `ST_Polygon` elements as a double-precision number.

`ST_Centroid()`

The function returns an `ST_Point` that is the center of an `ST_MultiPolygon`'s envelope.

`ST_PointOnSurface()`

The function returns an `ST_Point` that is guaranteed to be on the surface of one of its `ST_Polygon` elements.

Locale override

The external text representation of double-precision numbers in spatial data types follows the U.S. English locale (`en_us.8859-1`). In this standard, all text input must use dots (`.`) as decimal separators and must be single-byte ASCII, regardless of the locale. (Internally, the database server overrides the current locale with the U.S. English locale.)

For example, in many European locales, the decimal separator is a comma. You can keep using a non-English locale, but you must use dots in all text input, as follows:

```
ST_PointFromText('point zm (10.01 20.04 3.2 9.5)', 1)
```

This is true even if in your locale you normally use 3,2 instead of 3.2. External text always contains dots, regardless of the locale.

Spatial data types with SPL

You can use stored procedure language (SPL) with spatial data types.

SPL has two restrictions that might be relevant to working with spatial data:

- `LVARCHAR` variables in an SPL routine are restricted to 2K.
- SPL does not support a global variable defined on a UDT or complex type.

Chapter 3. Data exchange formats

You can use several different GIS data exchange formats for spatial data.

Related concepts:

“Overview of using spatial data” on page 1-2

Related reference:

“Insert data into a spatial column” on page 1-9

Well-known text representation

You can generate a geometry from the OGC well-known text (WKT) representation. The WKT is an ASCII text-formatted string that allows geometry to be exchanged in ASCII text form.

You can use the following functions in a third- or fourth-generation language (3GL or 4GL) program because they do not require the definition of any special program structures.

ST_GeomFromText()

The function creates an ST_Geometry from a text representation of any geometry type.

ST_PointFromText()

The function creates an ST_Point from a point text representation.

ST_LineFromText()

The function creates an ST_LineString from a linestring text representation.

ST_PolyFromText()

The function creates an ST_Polygon from a polygon text representation.

ST_MPointFromText()

The function creates an ST_MultiPoint from a multipoint representation.

ST_MLineFromText()

The function creates an ST_MultiLineString from a multilinestring representation.

ST_MPolyFromText()

The function creates an ST_MultiPolygon from a multipolygon representation.

ST_AsText()

The function converts an existing geometry into a text representation.

Related reference:

Appendix C, “OGC well-known text representation of geometry,” on page C-1

Well-known binary representation

You can generate a geometry from the OGC well-known binary (WKB) representation. The WKB representation is a contiguous stream of bytes. It permits geometry to be exchanged between a client application and an SQL database in binary form.

ST_GeomFromWKB()

The function creates an ST_Geometry from a WKB representation of any geometry type.

ST_PointFromWKB()

The function creates an ST_Point from a point WKB representation.

ST_LineFromWKB()

The function creates an ST_LineString from a linestring WKB representation.

ST_PolyFromWKB()

The function creates an ST_Polygon from a polygon WKB representation.

ST_MPointFromWKB()

The function creates an ST_MultiPoint from a multipoint WKB representation.

ST_MLineFromWKB()

The function creates an ST_MultiLineString from a multilinestring WKB representation.

ST_MPolyFromWKB()

The function creates an ST_MultiPolygon from a multipolygon WKB representation.

ST_AsBinary()

The function converts an existing geometry value into well-known binary representation.

Related reference:

Appendix C, "OGC well-known text representation of geometry," on page C-1

ESRI shape representation

You can generate a geometry from an *ESRI shape representation*. In addition to the two-dimensional representation supported by the Open GIS well-known binary representation, the ESRI shape representation also supports optional Z coordinates and measures.

The following functions generate geometry from an ESRI shape.

SE_GeomFromShape()

The function creates an ST_Geometry from a shape of any geometry type.

SE_PointFromShape()

The function creates an ST_Point from a point shape.

SE_LineFromShape()

The function creates an ST_LineString from a polyline shape.

SE_PolyFromShape()

The function creates an ST_Polygon from a polygon shape.

SE_MPointFromShape()

The function creates an ST_MultiPoint from a multipoint shape.

SE_MLineFromShape()

The function creates an ST_MultiLineString from a multipart polyline shape.

SE_MPolyFromShape()

The function creates an ST_MultiPolygon from a multipart polygon shape.

For all of these functions, the first argument is the shape representation and the second argument is the spatial reference identifier to assign to the **ST_Geometry**. For example, the **SE_GeomFromShape()** function has the following syntax:

```
SE_GeomFromShape(shapegeometry, SRID)
```

The **SE_AsShape()** function converts the geometry value into an ESRI shape representation.

Related reference:

Appendix E, “ESRI shape representation,” on page E-1

Geography Markup Language representation

You can generate a geometry from a Geography Markup Language (GML) representation. The GML can be represented as either GML2 (OGC GML standard 2.1.2) or GML3 (OGC GML standard 3.1.1). In addition to the two-dimensional representation supported by the Open GIS well-known binary representation, the GML representation also supports optional Z coordinates and measures.

The following functions generate a geometry from a GML string.

ST_GeomFromGML()

The function creates an **ST_Geometry** from a string of any geometry type.

ST_PointFromGML()

The function creates an **ST_Point** from a point string.

ST_LineFromGML()

The function creates an **ST_LineString** from a polyline string.

ST_PolyFromShape()

The function creates an **ST_Polygon** from a polygon string.

ST_MPointFromGML()

The function creates an **ST_MultiPoint** from a multipoint string.

ST_MLineFromGML()

The function creates an **ST_MultiLineString** from a multipart polyline string.

ST_MPolyFromGML()

The function creates an **ST_MultiPolygon** from a multipart polygon string.

For all of these functions, the first argument is the GML representation and the second optional argument is the spatial reference identifier to assign to the **ST_Geometry**. For example, the **ST_GeomFromGML()** function has the following syntax:

```
ST_GeomFromGML(gml_string, [SRID])
```

```
ST_GeomFromGML('<gml:Point srsName="ESPG:1234" srsDimension="2">  
  <gml:pos>10.02 20.01</gml:pos></gml:Point>', 1000)
```

The **SE_AsGML()** and **ST_AsGML()** functions convert the geometry value into a GML representation.

The **ST_EnvelopeAsGML()** function converts an **ST_Polygon** into a GML3 Envelope element.

Keyhole Markup Language representation

You can generate a geometry from a Keyhole Markup Language (KML) representation. KML is an XML-based schema for expressing geographic annotation and visualization on online maps and earth browsers.

The following functions generate a geometry from a KML string.

SE_EnvelopeFromKML()

The function creates an ST_Polygon from a KML LatLonBox string.

ST_GeomFromKML()

The function creates an ST_Geometry from a KML fragment.

ST_LineFromKML()

The function creates an ST_LineString from a KML LineString string.

ST_MLineFromKML()

The function creates an ST_MultiLineString from a KML MultiGeometry string.

ST_MPointFromKML()

The function creates an ST_MultiPoint from a KML MultiGeometry and Point combination string.

ST_MPolyFromKML()

The function creates an ST_MultiPolygon from a KML MultiGeometry and Polygon combination string.

ST_PointFromKML()

The function creates an ST_Point from a KML Point string.

ST_PolyFromKML()

The function creates an ST_Polygon from a KML Polygon string.

For most of these functions, the first argument is the KML representation and the second optional argument is the spatial reference identifier to assign to the ST_Geometry. For example, the **ST_LineFromKML()** function has the following syntax:

```
ST_LineFromKML(kmlstring lvarchar, SRID integer)
```

The **SE_AsKML()** and **ST_AsKML()** functions convert the geometry value into a GML representation.

The **ST_EnvelopeAsKML()** function converts an ST_Envelope bounding box into a KML LatLonBox string.

Chapter 4. R-tree indexes

An index organizes access to data so that entries can be found quickly, without searching every row. The R-tree access method enables you to index multidimensional objects.

Queries that use an index execute more quickly and provide a significant performance improvement. The R-tree access method speeds access to multidimensional data. It organizes data in a tree-shaped structure, with bounding boxes at the nodes. Bounding boxes indicate the farthest extent of the data that is connected to the subtree below.

A search using an R-tree index can quickly descend the tree to find objects in the general area of interest and then perform more exact tests on the objects themselves. An R-tree index can improve performance because it eliminates the need to examine objects outside the area of interest. Without an R-tree index, a query would need to evaluate every object to find those that match the query criteria.

When you create an index, you can specify an *access method* and an *operator class* (if you do not specify an access method, the default B-tree access method is used). The access method organizes the data in a way that speeds up access. The operator class is used by the optimizer to determine whether to use an index in a query.

To create an R-tree index, you must specify an operator class that supports an R-tree index on the data type you want to index. The operator class you use for IBM Informix spatial data types is **ST_Geometry_Ops**.

The B-tree access method creates a one dimensional ordering that speeds access to traditional numeric or character data. You can use B-tree to index a column of non-spatial data or to create a functional index on the results of a spatial function that returns numeric or character data. For example, you could create a functional B-tree index on the results of the **ST_NumPoints()** function because **ST_NumPoints()** returns an integer value.

Restriction: The B-tree access method indexes numeric and character data only. You cannot use the B-tree access method to index spatial data.

The syntax for creating an index is described in detail in the CREATE INDEX statement in *IBM Informix Guide to SQL: Syntax*.

For a detailed description of R-tree indexes, refer to the *IBM Informix R-Tree Index User's Guide*.

Syntax for creating an R-tree index

To use the R-tree access method, you create an index on a column of a spatial type.

Syntax

►►—CREATE INDEX—*index_name*—ON—*table_name*—————►

Element	Description
<i>column_name</i>	The name of the spatial column.
<i>index_name</i>	The name to give your index.
<i>index_options</i>	The index options are FRAGMENT BY and IN.
<i>parameters</i>	The parameters available for R-tree indexes are bottom_up_build, BOUNDING_BOX_INDEX, NO_SORT, sort_memory, and fill_factor.
<i>table_name</i>	The name of the table that contains the spatial column to index.

Restriction: You cannot rename databases that contain R-tree indexes.

The BOTTOM_UP_BUILD, BOUNDING_BOX_INDEX, and NO_SORT parameters affect the size of the index and the speed at which it is built. The following table shows the valid combinations of these parameters.

Table 4-1. Parameters of the CREATE INDEX statement for spatial data

Parameters clause of CREATE INDEX statement	Description
BOTTOM_UP_BUILD='no', BOUNDING_BOX_INDEX='no', NO_SORT='no'	Creates an index by inserting spatial objects into the R-tree one at a time. A copy of each object's in-row data is stored at the leaf level of the R-tree. This is the default if the DBSPACETEMP parameter in your onconfig file is not defined.
BOTTOM_UP_BUILD='no', BOUNDING_BOX_INDEX='yes', NO_SORT='no'	Creates a more compact index from the top down. Only the bounding boxes of each object are stored at the leaf level of the R-tree. No temporary dbspace is required.
BOTTOM_UP_BUILD='yes', BOUNDING_BOX_INDEX='no', NO_SORT='no'	Creates an index by sorting the spatial data and then building the R-tree from the bottom up. This is generally faster than building an index from the top down. This is the default if you have a temporary dbspace and it is specified by the DBSPACETEMP parameter in your onconfig file.
BOTTOM_UP_BUILD='yes', BOUNDING_BOX_INDEX='no', NO_SORT='yes'	Creates an index in less time <ul style="list-style-type: none"> Does not require a temporary dbspace Spatial data must be presorted, either by loading the data in a predetermined order or by creating a clustered functional B-tree index by using the SE_SpatialKey() function.

Table 4-1. Parameters of the CREATE INDEX statement for spatial data (continued)

Parameters clause of CREATE INDEX statement	Description
BOTTOM_UP_BUILD='yes', BOUNDING_BOX_INDEX='yes', NO_SORT='no'	Creates a more compact index from the bottom up, which is faster than building from the top down <ul style="list-style-type: none"> • This is the default if you have a temporary dbspace <i>and</i> it is specified by the DBSPACETEMP parameter in your onconfig file. • Spatial data need not be presorted.
BOTTOM_UP_BUILD='yes', BOUNDING_BOX_INDEX='yes', NO_SORT='yes'	Creates a more compact index in less time <ul style="list-style-type: none"> • Does not require a temporary dbspace • Spatial data must be presorted.

Related reference:

“The SE_SpatialKey() function” on page 8-103

Bottom-up versus top-down index builds

R-tree indexes are created using one of two options: *top-down build* or *bottom-up build*. When an index is built from the top down, spatial objects are inserted into the R-tree one at a time. Objects are grouped together in the R-tree according to their spatial proximity to one another.

When an index is built from the bottom up, objects are first sorted according to a numeric value which is generated by the **SE_SpatialKey()** function. Then the R-tree is built by inserting all objects into the leaf pages (the bottom level) of the tree in sorted order and then building a hierarchy of bounding boxes above the leaf pages.

An R-tree index can be built much more quickly from the bottom up than from the top down, typically 10 to 20 times faster. This increased speed comes at a price: you must create a temporary dbspace of sufficient size to sort all the spatial data in the table. To determine the size, use the following formula:

$$\text{Size (in bytes)} = \text{Number of rows in table} * 1000$$

Refer to your *IBM Informix Administrator's Guide* for more information about dbspaces.

The NO_SORT option eliminates the need for a temporary dbspace, but your spatial data *must* be presorted in the table. This means that it must be inserted into the table in sorted order, or sorted by means of a clustered B-tree index after it is loaded.

You should also note that the bottom-up build option only makes sense if you load all of your spatial data into a table before you create an R-tree index. There is no performance advantage to either build option if you create an index on an empty table and then insert data.

Depending on certain characteristics of your spatial data, an index built from the top down may be more effective than one built from the bottom up. Properties that can adversely affect a bottom-up built index include many objects that overlap

each other, or many objects that are very close together, such that the sort key produced by the `SE_SpatialKey()` function is the same value for a large number of objects.

Related reference:

“The `SE_SpatialKey()` function” on page 8-103

Functional R-tree indexes

Under certain conditions, you can create a functional R-tree index, using one of the several spatial data type functions. A functional index is built using the value returned by a function rather than the value of a column in a table.

For example, you can create an R-tree index on the centroids of the objects in a table, rather than on the objects themselves:

```
CREATE TABLE poly_tab (poly_col ST_Geometry);

CREATE INDEX centroid_idx ON poly_tab
  (ST_Centroid(poly_col) ST_Geometry_ops) USING RTREE;
```

You can use the following spatial data type functions in a functional index:

- `ST_Centroid()`
- `ST_EndPoint()`
- `ST_Envelope()`
- `SE_Midpoint()`
- `ST_Point()`
- `ST_PointN()`
- `ST_PointOnSurface()`
- `ST_StartPoint()`

Verify that the index is correctly built

To verify whether an index was successfully built, use the **oncheck** utility.

The output from **oncheck** for a successfully built index starts as shown:

```
WARNING: index check requires a s-lock on tables whose lock level is page.
Information for Partition num: 1049006
Node: Level 0, Pagenum 32, Usage 55.7%, No. of Children 11, right -1
```

Refer to your *IBM Informix Administrator's Guide* for information about using the **oncheck** utility.

The spatial operator class `ST_Geometry_Ops`

An operator class defines operators, called *strategy functions*, that can use an index. The operator class that the IBM Informix spatial data types require `ST_Geometry_Ops`.

Restriction: Do not use `rtree_ops`, the default R-tree operator class for the secondary access method.

The strategy functions for the `ST_Geometry_Ops` operator classes are:

- `ST_Contains()`
- `ST_Crosses()`
- `ST_Equals()`

- `SE_EnvelopesIntersect()`
- `ST_Intersects()`
- `SE_Nearest()`
- `SE_NearestBbox()`
- `ST_Overlaps()`
- `ST_Touches()`
- `ST_Within()`

How spatial operators use R-tree indexes

After you have created an index, it is considered by the query optimizer for any supported combination of argument types.

The index can be used regardless of whether the indexed column is the first or second argument. An operator with two parameters—also known as a *binary operator*—can take advantage of an index defined on a column that serves as one of its arguments.

Chapter 5. Run parallel queries

Running queries in parallel distributes the work for one aspect of a query among several processors and can dramatically improve performance.

You can use any of the spatial data type functions in a parallel query, except the **SE_BoundingBox()**, **SE_CreateSRID()**, **SE_MetadataInit()**, and **SE_Trace()** functions.

Related reference:

“Perform spatial queries” on page 1-12

Parallel query execution infrastructure

The database server creates and maintains various database objects to manage the execution of spatial queries in parallel.

Do not alter or delete any of the following items of infrastructure:

- The **SE_MetadataTable** table.
- The **SE_Metadata** opaque type.
- The metadata smart large object, which is stored in the default sbspace.
- The metadata `lhandle` file.
- The metadata memory cache.
- Triggers on the **spatial_references** table

You can use the **SE_MetadataInit()** function to re-initialize this infrastructure in case of difficulty.

Resolve problems with SE_MetadataInit()

In some rare circumstances, you might need to run the **SE_MetadataInit()** function to resolve problems.

Run the **SE_MetadataInit()** function to resolve the following problems:

- The metadata `lhandle` file is corrupted or missing, or cannot be created.
- The metadata smart large object is corrupted or missing.
- The metadata memory cache is corrupted or locked.

The **SE_MetadataInit()** function cannot be run in parallel.

Related reference:

“The **SE_MetadataInit()** function” on page 8-71

Execute parallel queries

To run queries in parallel, you must use the IBM Informix parallel database query (PDQ) feature.

To take full advantage of the performance enhancement PDQ provides, you need to use fragmented tables; table fragmentation allows you to store parts of a table on different disks.

See the *IBM Informix Performance Guide* for information about these topics. The *IBM Informix Performance Guide* contains topics that describe how the database server executes queries in parallel and how you can manage running queries in parallel; it also includes topics that describe how to work with fragmented tables.

Chapter 6. Estimate your spatial data

The total amount of space you need for spatial data is equal to the size of spatial tables plus the size of the spatial indexes.

The table size approximations discussed here should be within 100 MB accuracy for large tables; to make estimates of greater precision, refer to the *IBM Informix Performance Guide*.

Further tuning information is available at <http://www.ibm.com/software/data/informix/blades/spatial/>.

To estimate the amount of space you need for spatial data, add the results of the following calculations:

Estimating the storage space for the table

The total size of a spatial table is equal to the column sizes plus the dbspace overhead size multiplied by the number of rows.

To make a rough estimate of the storage space required by the spatial table:

1. Estimate the number of rows in the table.
2. Add the spatial column size, the non-spatial column size, and the dbspace overhead size together.
3. Multiply the sum by the estimated number of rows.

Estimate the size of the spatial column

The size of a spatial column depends on the points per feature, and coordinate factor, and the annotation size.

Estimate the size of the spatial column using the formula:

spatial column size = (average points per feature * coordinate factor)
+ annotation size

The *average points per feature* is the sum of all coordinate points required to render the features stored in a spatial table divided by the number of rows in the table. If the sum of all coordinates is difficult to obtain, use the approximations of the average number of points per feature for each data type in the table.

The collection data types (MultiPoints, MultiLineStrings, and MultiPolygons) are difficult to estimate. The numbers shown in the table are based on the types of data sets that these data types are most often applied to: broadcast patterns for MultiPoints, stream networks for MultiLineStrings, and island topology for MultiPolygons.

Data type	Average points per feature
Point	1
LineString (urban)	5
LineString (rural)	50
Polygon (urban)	7

Data type	Average points per feature
Polygon (rural)	150
MultiPoint	50
MultiLineString	250
MultiPolygon	1000

The *coordinate factor* is based on the dimensions of the coordinates stored by the spatial column. Select the coordinate factor from the table below.

Coordinate type	Coordinate factor
XY	4.8
XYZ	7.2
XY and measures	7.2
XYZ and measures	9.6

If your layer includes annotation, set the *annotation size* to 300 bytes (this is the average space required to store most annotation). This includes the space required to store text, placement geometry, lead line geometry, and various attributes describing the annotation's size and font.

Estimate the size of non-spatial columns

You can estimate the row size of fixed-sized columns by querying the **systables** system catalog table. You must estimate the average size of variable length columns.

To determine the size of the remaining columns of a spatial table, create the table without the spatial column and query the **rowsize** column of the **systables** table. In this example, a table called **lots** is created with three columns:

```
create table lots (lot_id integer,
                 owner_name varchar(128),
                 owner_address varchar(128))
```

Selecting the row size for the **lots** table from **systables** returns a value of 262 bytes:

```
select rowsize from systables where tablename = 'lots';
```

```
262
```

Tables containing variable length columns of type VARCHAR or NVARCHAR require the row size to be reduced to reflect the actual length of the data stored. In this example, the **owner_name** and **owner_address** columns are variable length VARCHAR columns and can occupy up to 129 bytes each (128 bytes for data plus an extra byte for the null terminator). The average size of the owner name is actually 68 bytes, and the average size of the address is 102 bytes. Therefore, the estimated row size should be reduced to 174 bytes.

Estimate dbspace overhead requirements

The amount of dbspace overhead that spatial tables require depends on the number of rows.

Spatial tables with more than 10,000 rows require about 200 bytes of overhead per row.

Spatial tables with fewer than 10,000 rows but more than 1,000 rows require 300 bytes per row.

Spatial tables with fewer than 1,000 rows require 400 bytes per row.

Estimating the smart large object storage space

A spatial data value is stored in row if the value is less than or equal to 930 bytes. However, if the value is greater than 930 bytes, only a pointer of 64 bytes is stored in row. This pointer refers to the smart large object in which the actual data is stored.

Important: Store sbspaces on a disk separate from both the table and the indexes.

To estimate the amount of smart large object storage space:

1. Determine the smart large object ratio using the following formula:
$$\text{smart large object ratio} = (\text{spatial column size} / 1920)$$

The smart large object ratio cannot be greater than 1. So if the smart large object ratio you calculate is greater than one, set it to 1.
2. Multiply your smart large object ratio by the number of rows in your table to obtain the amount of smart large object space used by your table:
$$\text{smart large object space} = (\text{smart large object ratio}) * \text{number of rows}$$
3. Determine the amount of in-line table space required using the following formula:
$$\text{in-line space} = (\text{size of spatial table}) - (\text{smart large object space})$$

Estimating the size of spatial indexes

You can calculate the size of your spatial indexes based on the size of your spatial columns and dbspace overhead space size.

The ArcSDE service creates and maintains two indexes whenever you add a spatial column to one of your tables. The ArcSDE service creates an R-tree index on the spatial column and a B-tree index on the SE_ROW_ID INTEGER column. The R-tree index is named a_n_ix1 and the B-tree index is named a_n_ix2 , where n is the spatial column's layer number assigned by the ArcSDE service.

The indexes are three percent greater than the dbspace overhead space and spatial column size of the table.

To calculate the index space requirements:

1. Combine the spatial column size and the dbspace overhead space size.
2. Multiply this sum by the number of rows in the table.
3. Multiply the result of step 2 by 1.03.

Chapter 7. Determine spatial relationships and transform geometries

Use specific spatial data type functions to perform operations on spatial data.

These topics describe spatial data type functions that:

- Determine spatial relationships
- Produce a new geometry
- Transform geometries

Functions that determine spatial relationships

You can use some spatial data type functions to determine whether a specific relationship exists between a pair of geometries.

The distance separating a hazardous waste disposal site and a school is an example of a spatial relationship.

The Dimensionally Extended 9 Intersection Model (DE-9IM) is a mathematical approach that defines the pair-wise spatial relationship between geometries of different types and dimensions. If you are interested in using this model to understand how the functions in this section operate, refer to “The Dimensionally Extended 9 Intersection Model” on page 7-15.

The `ST_Equals()` function

The `ST_Equals()` function returns t (TRUE) if two geometries of the same type have identical X,Y coordinate values.

Figure 7-1. Equal geometries

Related reference:

“The ST_Equals() function” on page 8-42

The ST_Disjoint() function

The **ST_Disjoint()** function returns t (TRUE) if two geometries do not intersect, overlap, or touch each other.

Figure 7-2. Disjoint geometries

Related reference:

“The ST_Disjoint() function” on page 8-33

The ST_Intersects() function

The **ST_Intersects()** function returns t (TRUE) if two geometries intersect. **ST_Intersects()** returns the opposite result of **ST_Disjoint()**.

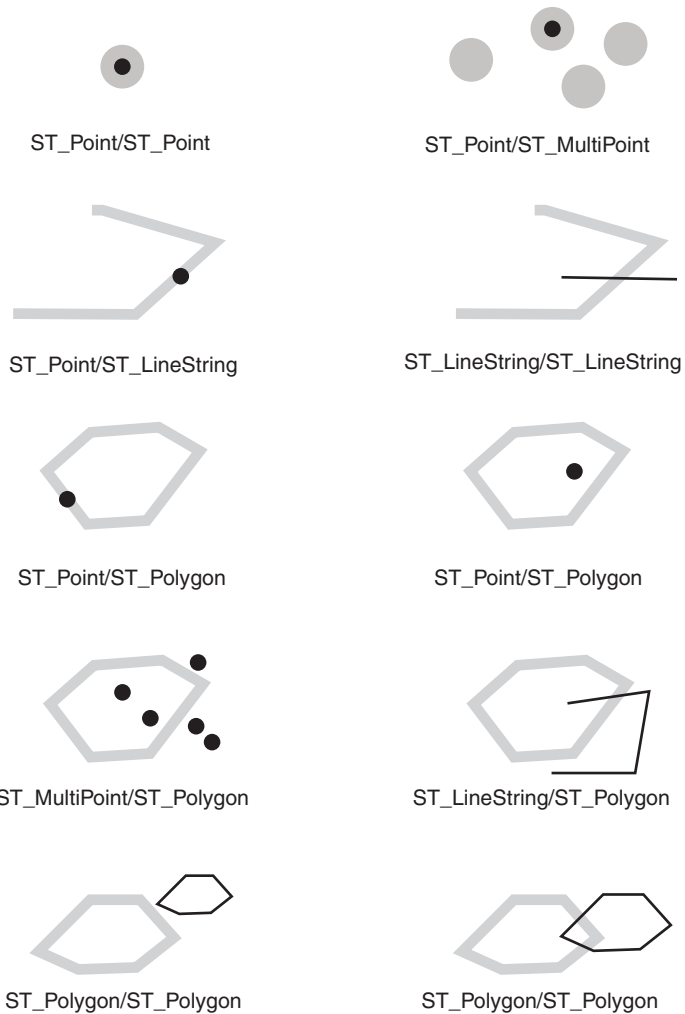

Figure 7-3. A selection of geometries that intersect

Related reference:

“The ST_Intersects() function” on page 8-56

The ST_Touches() function

The **ST_Touches()** function returns t (TRUE) when the interiors of two geometries do not intersect and the boundary of either geometry intersects the other’s interior or boundary. At least one geometry must be an ST_LineString, ST_Polygon, ST_MultiLineString, or ST_MultiPolygon type.

Figure 7-4. Touching geometries

Related reference:

“The ST_Touches() function” on page 8-108

The ST_Overlaps() function

The **ST_Overlaps()** function determines whether two geometries overlap.

ST_Overlaps() returns t (TRUE) only for geometries of the same dimension and only when their intersection set results in a geometry of the same dimension. In other words, if the intersection of two ST_Polygon types results in an ST_Polygon, then **ST_Overlaps()** returns t (TRUE).

Figure 7-5. Overlapping geometries

Related reference:

“The ST_Overlaps() function” on page 8-87

The ST_Crosses() function

The **ST_Crosses()** function determines whether the following pairs of geometries cross each other:

ST_MultiPoint and ST_Polygon; ST_MultiPoint and ST_LineString; ST_LineString and ST_LineString; ST_LineString and ST_Polygon; and ST_LineString and ST_MultiPolygon.

Figure 7-6. Crossing geometries

Related reference:

“The ST_Crosses() function” on page 8-29

The ST_Within() function

The **ST_Within()** function returns t (TRUE) if the first geometry is completely within the second geometry.

The boundary and interior of the first geometry are not allowed to intersect the exterior of the second geometry. **ST_Within()** tests for the exact opposite result of **ST_Contains()**.

Figure 7-7. The *ST_Within* function

Related reference:

“The *ST_Within()* function” on page 8-113

The *ST_Contains()* function

The *ST_Contains()* function returns t (TRUE) if the second geometry is completely contained by the first geometry.

The boundary and interior of the second geometry are not allowed to intersect the exterior of the first geometry. *ST_Contains()* returns the opposite result of *ST_Within()*.

Figure 7-8. Contained geometries

Related reference:

“The `ST_Contains()` function” on page 8-22

Functions that produce a new geometry

Some functions compare two existing geometries and return a new geometry based on how the two geometries are related.

For example, the `ST_Difference()` function returns that portion of the first geometry that is not intersected or overlapped by the second.

The `ST_Intersection()` function

The `ST_Intersection()` function returns the intersection set of two geometries.

The intersection set is returned as a collection that is the minimum dimension of the source geometries. For example, for an `ST_LineString` that intersects an `ST_Polygon`, the `ST_Intersection()` function returns that portion of the `ST_LineString` common to the interior and boundary of the `ST_Polygon` as an `ST_MultiLineString`. The `ST_MultiLineString` contains more than one `ST_LineString` if the source `ST_LineString` intersects the `ST_Polygon` with two or more discontinuous segments.

If the geometries do not intersect or if the intersection results in a dimension less than both source geometries, an empty geometry is returned. The following figure illustrates some examples of the `ST_Intersection()` function.

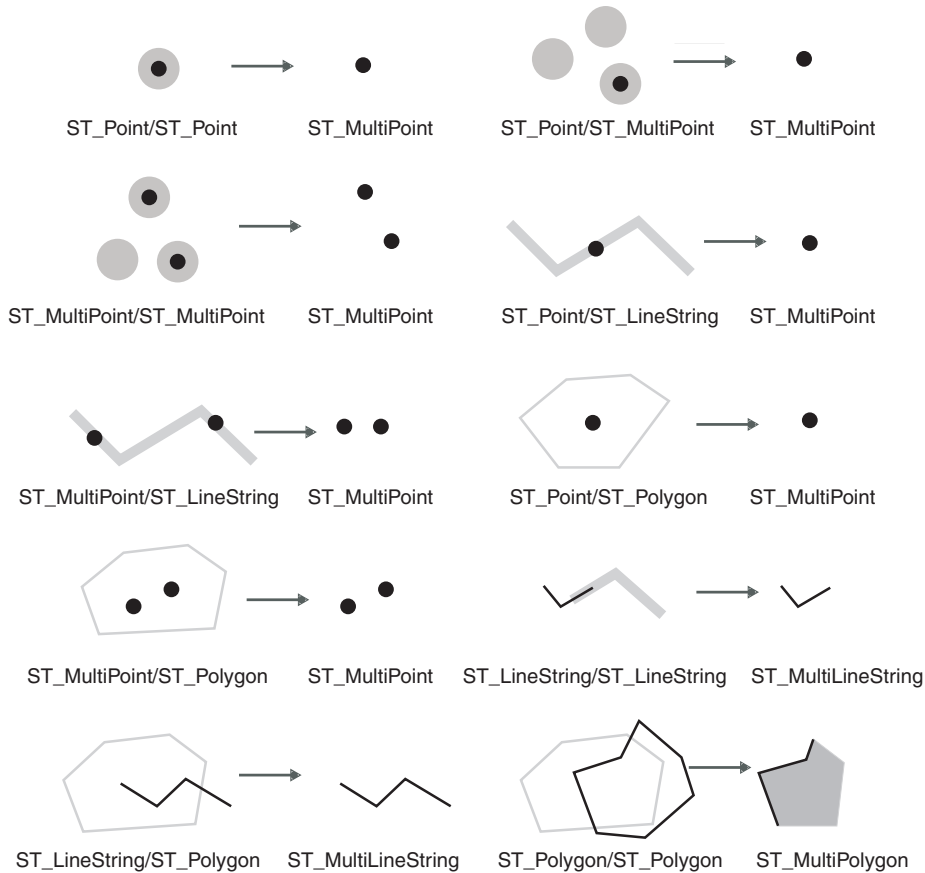

Figure 7-9. Intersection sets of geometries

Related reference:

“The ST_Intersection() function” on page 8-54

The ST_Difference() function

The **ST_Difference()** function returns the portion of the primary geometry that is not intersected by the secondary geometry—the logical AND NOT of space.

The **ST_Difference()** function only operates on geometries of like dimension and returns an ST_GeomCollection (ST_MultiPoint, ST_MultiLineString, or ST_MultiPolygon) that has the same dimension as the source geometries. In the event that the source geometries are equal, an empty geometry is returned.

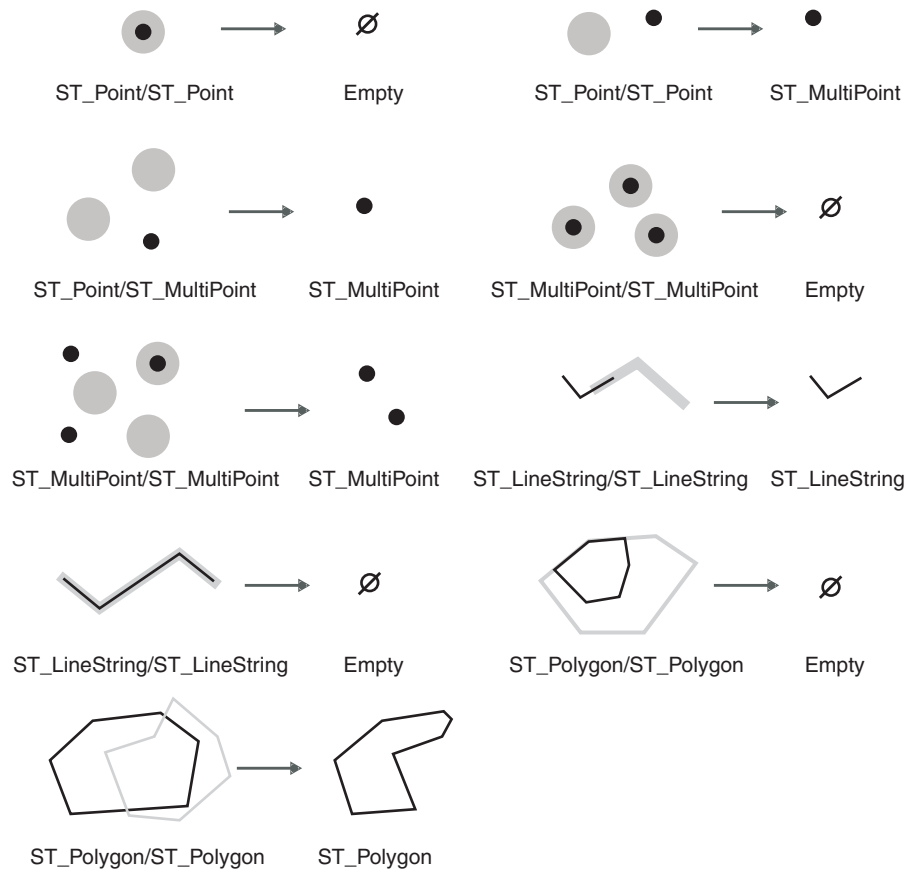

Figure 7-10. The ST_Difference() function

Related reference:

“The ST_Difference() function” on page 8-31

The ST_Union() function

The **ST_Union()** function returns the union set of two geometries—the Boolean logical OR of space.

The source geometries must have the same dimension. **ST_Union()** returns the result as an ST_GeomCollection (ST_MultiPoint, ST_MultiLineString, or ST_MultiPolygon).

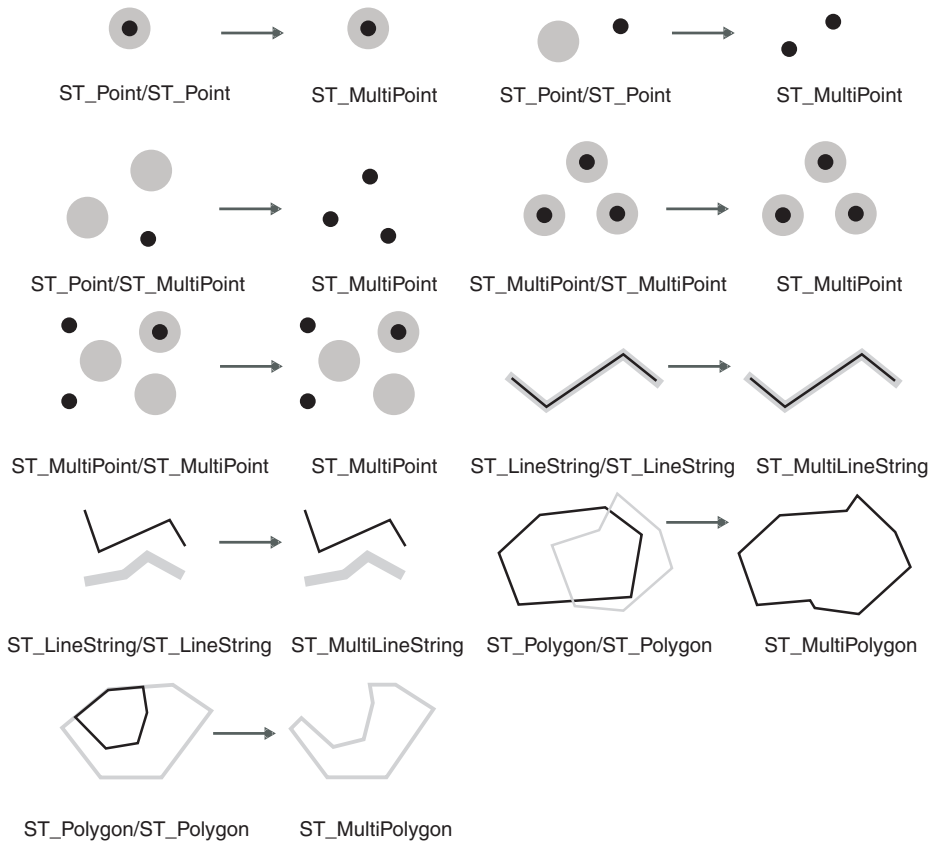

Figure 7-11. The union set of two geometries

Related reference:

“The `ST_Union()` function” on page 8-111

The `ST_SymDifference()` function

The `ST_StartPoint()` function returns the symmetric difference of two geometries—the logical XOR of space (the portions of the source geometries that are not part of the intersection set).

The source geometries must have the same dimension. If the geometries are equal, the `ST_StartPoint()` function returns an empty geometry; otherwise, the function returns the result as an `ST_GeomCollection` (`ST_MultiPoint`, `ST_MultiLineString`, or `ST_MultiPolygon`).

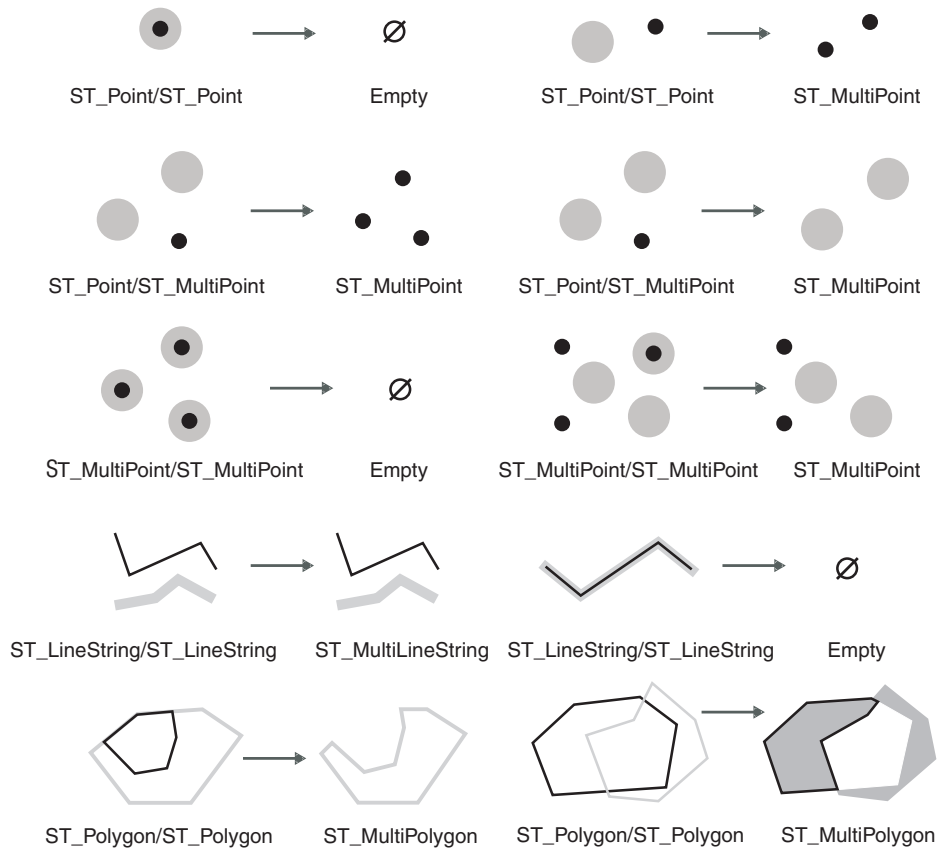

Figure 7-12. The symmetric difference of geometries

Related reference:

“The ST_SymDifference() function” on page 8-106

The SE_Dissolve() function

The SE_Dissolve() function is an aggregate function that computes the union of geometries of the same dimension (if there is just one geometry that satisfies your query, it is returned unaltered).

Figure 7-13. Geometries resulting from use of SE_Dissolve()

Related reference:

“The SE_Dissolve() function” on page 8-34

Functions that transform geometries

Some spatial data type functions generate a new geometry from an existing geometry and a formula.

The ST_Buffer function

The **ST_Buffer()** function generates a geometry by encircling a geometry at a specified distance.

A single polygon results when a primary geometry is buffered or when the buffer polygons of a collection are close enough to overlap. When enough separation exists between the elements of a buffered collection, individual buffer ST_Polygons result in an ST_MultiPolygon.

The **ST_Buffer()** function accepts both positive and negative distances, but only geometries with a dimension of 2 (ST_Polygon and ST_MultiPolygon) can apply a negative buffer. The absolute value of the buffer distance is used when the dimension of the source geometry is less than 2 (all geometries that are neither ST_Polygon nor ST_MultiPolygon). Generally speaking, positive buffer distances generate polygon rings that are away from the center of the source geometry, and for the exterior ring of a ST_Polygon or ST_MultiPolygon, toward the center when the distance is negative. For interior rings of an ST_Polygon or ST_MultiPolygon, the buffer ring is toward the center when the buffer distance is positive and away from the center when it is negative.

The buffering process merges buffer polygons that overlap. Negative distances greater than one-half the maximum interior width of a polygon result in an empty geometry.

As shown in the following figure, **ST_Buffer()** generates a polygon or a multipolygon surrounding a given geometry at a specified radius.

Figure 7-14. Buffers generated by the *ST_Buffer()* function

Related reference:

“The *ST_Buffer()* function” on page 8-19

The **SE_LocateAlong()** function

For geometries that have measures, the location of a particular measure can be found with the **SE_LocateAlong()** function.

SE_LocateAlong() returns the location as an *ST_MultiPoint*.

If the source geometry's dimension is 0 (for *ST_Point* and *ST_MultiPoint*), only points with a matching measure value are returned as an *ST_MultiPoint*. However, for source geometries whose dimension is greater than 0, the location is interpolated. For example, if the requested measure value is 5.5 and the *ST_LineString* vertices have measures of 3, 4, 5, 6, and 7, an interpolated point that falls exactly halfway between the vertices with measure values 5 and 6 is returned.

SE_LocateAlong() locates a point on a linestring by interpolating the given measure value, if necessary. The following figure shows a case where a point with measure 5.5 is interpolated halfway between the vertices of the *ST_LineString* with measures 5 and 6. For *ST_MultiPoints*, an exact match is required. In the case of the above *ST_MultiPoint*, **SE_LocateAlong()** returns the point that has measure 5.5.

Figure 7-15. The *SE_LocateAlong* function

The *SE_LocateBetween()* function

The *SE_LocateBetween()* function returns the set of paths or locations that lie between two measure values from a source geometry.

If the source geometry dimension is 0, *SE_LocateBetween()* returns an *ST_MultiPoint* consisting of all points whose measures lie between the two source measures.

For source geometries whose dimension is greater than 0, *SE_LocateBetween()* returns an *ST_MultiLineString* if a path can be interpolated; otherwise, *SE_LocateBetween()* returns an *ST_MultiPoint* containing the point locations.

An empty point is returned whenever *SE_LocateBetween()* cannot interpolate a path or find a location between the measures.

SE_LocateBetween() performs an inclusive search of the geometries; therefore, the geometry measures must be greater than or equal to the *from* measure and less than or equal to the *to* measure.

In the following figure, *SE_LocateBetween()* returns an *ST_MultiLineString* that is between measures 4.3 and 6.9.

Figure 7-16. The *SE_LocateBetween* function

The *ST_ConvexHull()* function

The *ST_ConvexHull()* function returns the convex hull polygon of any geometry that has at least three vertices forming a convex.

Creating a convex hull is often the first step when tessellating a set of points to create a triangulated irregular network (TIN). If vertices of the geometry do not form a convex, *ST_ConvexHull()* returns a null.

ST_ConvexHull() generates an *ST_Polygon* value from the convex hull of three of the geometries pictured in the following figure. *ST_ConvexHull()* returns a null for

the two-point `ST_LineString` because it does not form a convex hull.

Figure 7-17. The `ST_ConvexHull()` function.

Related reference:

“The `ST_ConvexHull()` function” on page 8-23

The `SE_Generalize()` function

The `SE_Generalize()` function reduces the number of vertices in an `ST_LineString`, `ST_MultiLineString`, `ST_Polygon`, or `ST_MultiPolygon` while preserving the general character of the geometric shape.

Figure 7-18. Geometries resulting from use of `SE_Generalize()`

Related reference:

“The `SE_Generalize()` function” on page 8-44

The Dimensionally Extended 9 Intersection Model

The Dimensionally Extended 9 Intersection Model (DE-9IM) developed by Clementini and others, dimensionally extends the 9 Intersection Model of Egenhofer and Herring. DE-9IM is a mathematical approach that defines the pair-wise spatial relationship between geometries of different types and dimensions. This model expresses spatial relationships among all types of

geometry as pair-wise intersections of their interior, boundary, and exterior with consideration for the dimension of the resulting intersections.

Given geometries a and b , $I(a)$, $B(a)$, and $E(a)$ represent the interior, boundary, and exterior of a , and $I(b)$, $B(b)$, and $E(b)$ represent the interior, boundary, and exterior of b . The intersections of $I(a)$, $B(a)$, and $E(a)$ with $I(b)$, $B(b)$, and $E(b)$ produce a 3-by-3 matrix. Each intersection can result in geometries of different dimensions. For example, the intersection of the boundaries of two polygons could consist of a point and a linestring, in which case the `dim()` function would return the maximum dimension of 1.

The `dim` function returns a value of -1, 0, 1, or 2. The -1 corresponds to the null set that is returned when no intersection was found or `dim()`.

Table 7-1. Results of intersections

	Interior	Boundary	Exterior
Interior	<code>dim(I(a)I(b))</code>	<code>dim(I(a)B(b))</code>	<code>dim(I(a)E(b))</code>
Boundary	<code>dim(B(a)I(b))</code>	<code>dim(B(a)B(b))</code>	<code>dim(B(a)E(b))</code>
Exterior	<code>dim(E(a)I(b))</code>	<code>dim(E(a)B(b))</code>	<code>dim(E(a)E(b))</code>

The results of the spatial relationship for the functions described in “Functions that determine spatial relationships” on page 7-1 can be understood or verified by comparing the results with a pattern matrix that represents the acceptable values for the DE-9IM.

The pattern matrix contains the acceptable values for each of the intersection matrix cells. The possible pattern values are:

- T** An intersection must exist; `dim` = 0, 1, or 2.
- F** An intersection must not exist; `dim` = -1.
- *** It does not matter if an intersection exists or not; `dim` = -1, 0, 1, or 2.
- 0** An intersection must exist and its maximum dimension must be 0; `dim` = 0.
- 1** An intersection must exist and its maximum dimension must be 1; `dim` = 1.
- 2** An intersection must exist and its maximum dimension must be 2; `dim` = 2. For example, the pattern matrix of the `ST_Within()` function for geometry combinations has the following form:

Table 7-2. Pattern matrix of the ST_Within() function

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	F
	Boundary	*	*	F
	Exterior	*	*	*

Simply put, the `ST_Within()` function returns TRUE when the interiors of both geometries intersect, and the interior and boundary of geometry a does not intersect the exterior of geometry b . All other conditions do not matter.

The ST_Equals() function

The DE-9IM pattern matrix for the **ST_Equals()** function ensures that the interiors intersect and that no interior or boundary of either geometry intersects the exterior of the other.

Table 7-3. The DE-9IM pattern matrix for the *ST_Equals()* function

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	F
	Boundary	*	*	F
	Exterior	F	F	*

Related reference:

“The ST_Equals() function” on page 8-42

The ST_Disjoint() function

The **ST_Disjoint()** function pattern matrix simply states that neither the interiors nor the boundaries of either geometry intersect.

Table 7-4. Pattern matrix for the *ST_Disjoint()* function

		b		
		Interior	Boundary	Exterior
a	Interior	F	F	*
	Boundary	F	F	*
	Exterior	*	*	*

Related reference:

“The ST_Disjoint() function” on page 8-33

The ST_Intersects() function

The **ST_Intersects()** function returns TRUE if the conditions of any of the following pattern matrices returns TRUE.

The **ST_Intersects()** function returns TRUE if the interiors of both geometries intersect.

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	*
	Boundary	*	*	*
	Exterior	*	*	*

The **ST_Intersects()** function returns TRUE if the boundary of the first geometry intersects the boundary of the second geometry.

		b		
		Interior	Boundary	Exterior
a	Interior	*	T	*

		b		
		Interior	Boundary	Exterior
a	Boundary	*	*	*
	Exterior	*	*	*

The **ST_Intersects()** function returns TRUE if the boundary of the first geometry intersects the interior of the second.

		b		
		Interior	Boundary	Exterior
a	Interior	*	*	*
	Boundary	T	*	*
	Exterior	*	*	*

The **ST_Intersects()** function returns TRUE if the boundaries of either geometry intersect.

		b		
		Interior	Boundary	Exterior
a	Interior	*	*	*
	Boundary	*	T	*
	Exterior	*	*	*

Related reference:

“The ST_Intersects() function” on page 8-56

The ST_Touches() function

The pattern matrices show us that the **ST_Touches()** function returns TRUE when the interiors of the geometry do not intersect, and the boundary of either geometry intersects the other's interior or boundary.

The **ST_Touches()** function returns TRUE if the boundary of one geometry intersects the interior of the other but the interiors do not intersect.

		b		
		Interior	Boundary	Exterior
a	Interior	F	T	*
	Boundary	*	*	*
	Exterior	*	*	*

The **ST_Touches()** function returns TRUE if the boundary of one geometry intersects the interior of the other but the interiors do not intersect.

		b		
		Interior	Boundary	Exterior
a	Interior	F	*	*
	Boundary	T	*	*

	b		
	Interior	Boundary	Exterior
Exterior	*	*	*

The **ST_Touches()** function returns TRUE if the boundaries of both geometries intersect but the interiors do not.

	b		
	Interior	Boundary	Exterior
Interior	F	*	*
a Boundary	*	T	*
Exterior	*	*	*

Related reference:

“The ST_Touches() function” on page 8-108

The ST_Overlaps() function

The **ST_Overlaps()** function returns TRUE if the intersection of the objects results in an object of the same dimension but not equal to either source object.

This pattern matrix applies to ST_Polygon and ST_Polygon; ST_MultiPoint and ST_MultiPoint; and ST_MultiPolygon and ST_MultiPolygon overlaps. For these combinations, the **ST_Overlaps()** function returns TRUE if the interior of both geometries intersects the other's interior and exterior.

	b		
	Interior	Boundary	Exterior
Interior	T	*	T
a Boundary	*	*	*
Exterior	T	*	*

This pattern matrix applies to ST_LineString and ST_LineString; and to ST_MultiLineString and ST_MultiLineString overlaps. In this case the intersection of the geometries must result in a geometry that has a dimension of 1 (another ST_LineString or ST_MultiLineString). If the dimension of the intersection of the interiors had resulted in 0 (a point), the **ST_Overlaps()** function would return FALSE; however, the **ST_Crosses()** function would have returned TRUE.

	b		
	Interior	Boundary	Exterior
Interior	1	*	T
a Boundary	*	*	*
Exterior	T	*	*

Related reference:

“The ST_Overlaps() function” on page 8-87

The ST_Crosses() function

The **ST_Crosses()** function returns TRUE if the intersection object contains points that are interior to both source geometries, but is not equal to either of the source objects.

This **ST_Crosses()** function pattern matrix applies to ST_MultiPoint and ST_LineString; ST_MultiPoint and ST_MultiLineString; ST_MultiPoint and ST_Polygon; ST_MultiPoint and ST_MultiPolygon; ST_LineString and ST_Polygon; and ST_LineString and ST_MultiPolygon. The matrix states that the interiors must intersect and that at least the interior of the primary (geometry *a*) must intersect the exterior of the secondary (geometry *b*).

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	T
	Boundary	*	*	*
	Exterior	*	*	*

This **ST_Crosses()** function matrix applies to ST_LineString and ST_LineString; ST_LineString and ST_MultiLineString; and ST_MultiLineString and ST_MultiLineString. The matrix states that the dimension of the intersection of the interiors must be 0 (intersect at a point). If the dimension of this intersection was 1 (intersect at a linestring), the **ST_Crosses()** function would return FALSE but the **ST_Overlaps()** function would return TRUE.

		b		
		Interior	Boundary	Exterior
a	Interior	0	*	*
	Boundary	*	*	*
	Exterior	*	*	*

Related reference:

“The ST_Crosses() function” on page 8-29

The ST_Within() function

The **ST_Within()** function pattern matrix states that the interiors of both geometries must intersect and that the interior and boundary of the primary geometry (geometry *a*) must not intersect the exterior of the secondary (geometry *b*).

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	F
	Boundary	*	*	F
	Exterior	*	*	*

Related reference:

“The ST_Within() function” on page 8-113

The ST_Contains() function

The pattern matrix of the **ST_Contains()** function states that the interiors of both geometries must intersect, and that the interior and boundary of the secondary (geometry *b*) must not intersect the exterior of the primary (geometry *a*).

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	*
	Boundary	*	*	*
	Exterior	F	F	*

“The ST_Contains() function” on page 8-22

Chapter 8. Spatial functions

Most spatial data functions are compliant with OpenGIS and ISO/SQLMM standards and have the prefix `ST_`. Some spatial data functions extend the OpenGIS and ISO/SQLMM standards and have the prefix `SE_`.

The following OpenGIS and ISO/SQLMM-compliant functions replace deprecated functions that extend the standards:

Table 8-1. Compliant functions that replace extension functions

Compliant function	Extension function
<code>ST_Is3D()</code>	<code>SE_Is3D()</code>
<code>ST_IsMeasured()</code>	<code>SE_IsMeasured()</code>
<code>ST_LocateAlong()</code>	<code>SE_LocateAlong()</code>
<code>ST_LocateBetween()</code>	<code>SE_LocateBetween()</code>
<code>ST_M()</code>	<code>SE_M()</code>
<code>ST_Z()</code>	<code>SE_Z()</code>
<code>ST_MaxM()</code>	<code>SE_MMax()</code>
<code>ST_MinM()</code>	<code>SE_MMin()</code>
<code>ST_MaxX()</code>	<code>SE_XMax()</code>
<code>ST_MinX()</code>	<code>SE_XMin()</code>
<code>ST_MaxY()</code>	<code>SE_YMax()</code>
<code>ST_MinY()</code>	<code>SE_YMin()</code>
<code>ST_MaxZ()</code>	<code>SE_ZMax()</code>
<code>ST_MaxZ()</code>	<code>SE_ZMin()</code>

Summary of spatial functions by task type

The spatial data type functions do different types of tasks, such as generating different formats, manipulating or comparing data, and obtaining information about data.

The following table shows the spatial data type functions arranged by task type.

Table 8-2. Spatial functions by task type

Function task type	Description	Function name
Generate a geometry from a well-known text representation.	Takes a well-known text representation and returns an ST_Geometry using SRID 0	"The ST_WKTToSQL() function" on page 8-115
	Takes a well-known text representation and returns an ST_Geometry	"The ST_GeomFromText() function" on page 8-50
	Takes a well-known text representation and returns an ST_Point	"The ST_PointFromText() function" on page 8-94
	Takes a well-known text representation and returns an ST_LineString	"The ST_LineFromText() function" on page 8-66
	Takes a well-known text representation and returns an ST_Polygon	"The ST_PolyFromText() function" on page 8-99
	Takes a well-known text representation and returns an ST_MultiLine	"The ST_MLineFromText() function" on page 8-75
	Takes a well-known text representation and returns an ST_MultiPoint	"The ST_MPointFromText() function" on page 8-78
	Takes a well-known text representation and returns an ST_MultiPolygon	"The ST_MPolyFromText() function" on page 8-82
Generate a geometry from a well-known binary representation.	Takes a well-known binary representation and returns an ST_Geometry using SRID 0	"The ST_WKBToSQL() function" on page 8-114
	Takes a well-known binary representation and returns an ST_Geometry	"The ST_GeomFromWKB() function" on page 8-51
	Takes a well-known binary representation and returns an ST_Point	"The ST_PointFromWKB() function" on page 8-94
	Takes a well-known binary representation and returns an ST_LineString	"The ST_LineFromWKB() function" on page 8-67
	Takes a well-known binary representation and returns an ST_Polygon	"The ST_PolyFromWKB() function" on page 8-99
	Takes a well-known binary representation and returns an ST_MultiLine	"The ST_MLineFromWKB() function" on page 8-75
	Takes a well-known binary representation and returns an ST_MultiPoint	"The ST_MPointFromWKB() function" on page 8-79
	Takes a well-known binary representation and returns an ST_MultiPolygon	"The ST_MPolyFromWKB() function" on page 8-83

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Generate a geometry from an ESRI shape representation.	Takes an ESRI shape representation and returns an ST_Geometry using SRID 0	"The SE_ShapeToSQL() function" on page 8-102
	Takes an ESRI shape representation and returns an ST_Geometry	"The SE_GeomFromShape() function" on page 8-49
	Takes an ESRI shape representation and returns an ST_Point	"The SE_PointFromShape() function" on page 8-93
	Takes an ESRI shape representation and returns an ST_LineString	"The SE_LineFromShape() function" on page 8-65
	Takes an ESRI shape representation and returns an ST_Polygon	"The SE_PolyFromShape() function" on page 8-98
	Takes an ESRI shape representation and returns an ST_MultiLine	"The SE_MLineFromShape() function" on page 8-74
	Takes an ESRI shape representation and returns an ST_MultiPoint	"The SE_MPointFromShape() function" on page 8-78
	Takes an ESRI shape representation and returns an ST_MultiPolygon	"The SE_MPolyFromShape() function" on page 8-81
Generate a geometry from a GML representation.	Takes a GML2 or GML3 string representation of an envelope and returns an ST_Polygon	"The ST_EnvelopeFromGML() function" on page 8-40
	Takes a GML2 or GML3 string representation and returns an ST_Geometry	"The ST_GeomFromGML() function" on page 8-46
	Takes a GML2 or GML3 string representation and returns an ST_LineString	"The ST_LineFromGML() function" on page 8-64
	Takes a GML2 or GML3 string representation and returns an ST_MultiLineString	"The ST_MLineFromGML() function" on page 8-72
	Takes a GML2 or GML3 string representation and returns an ST_MultiPoint	"The ST_MPointFromGML() function" on page 8-76
	Takes a GML2 or GML3 string representation and returns an ST_MultiPolygon	"The ST_MPolyFromGML() function" on page 8-80
	Takes a GML2 or GML3 string representation and returns an ST_Point	"The ST_PointFromGML() function" on page 8-92
	Takes a GML2 or GML3 string representation and returns an ST_Polygon	"The ST_PolyFromGML() function" on page 8-97

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Generate a geometry from a KML representation.	Takes a KML LatLonBox string representation and returns an ST_Polygon	“The SE_EnvelopeFromKML() function” on page 8-40
	Takes a KML fragment string representation and returns an ST_Geometry	“The ST_GeomFromKML() function” on page 8-49
	Takes a KML LineString string representation and returns an ST_LineString	“The ST_LineFromKML() function” on page 8-65
	Takes a KML MultiGeometry string representation and returns an ST_MultiLineString	“The ST_MLineFromKML() function” on page 8-73
	Takes a KML MultiGeometry and Point combination string representation and returns an ST_MultiPoint	“The ST_MPointFromKML() function” on page 8-77
	Takes a KML MultiGeometry and Polygon combination string representation and returns an ST_MultiPolygon	“The ST_MPolyFromKML() function” on page 8-81
	Takes a KML Point string representation and returns an ST_Point	“The ST_PointFromKML() function” on page 8-93
	Takes a KML Polygon string representation and returns an ST_Polygon	“The ST_PolyFromKML() function” on page 8-97
Convert a geometry to an external format.	Returns the well-known text representation of a geometry object	“The ST_AsText() function” on page 8-16
	Returns the well-known binary representation of a geometry object	“The ST_AsBinary() function” on page 8-10
	Returns the ESRI shape representation of a geometry object	“The SE_AsShape() function” on page 8-15
	Returns the GML representation of a geometry object	“The SE_AsGML() function” on page 8-11 or “The ST_AsGML() function” on page 8-12
	Returns the GML3 Envelope element of an ST_Envelope object	“The ST_EnvelopeAsGML() function” on page 8-39
	Returns the KML representation of a geometry object	“The ST_AsKML() function” on page 8-14 or “The SE_AsKML() function” on page 8-13
	Returns the KML LatLonBox of an ST_Envelope object	“The SE_EnvelopeAsKML() function” on page 8-39
Manipulate the ST_Point data type.	Creates an ST_Point data type from an X and Y coordinate	“The ST_Point() function” on page 8-91
	Returns the X coordinate of a point	“The ST_X() function” on page 8-116
	Returns the Y coordinate of a point	“The ST_Y() function” on page 8-117
	Returns the Z coordinate of a point	“The ST_Z function” on page 8-117
	Returns the measure value of a point	“The ST_M() function” on page 8-70

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Manipulate the ST_LineString and ST_MultiLineString data types.	Returns the first point	“The ST_StartPoint() function” on page 8-105
	Returns the midpoint	“The SE_Midpoint() function” on page 8-72
	Returns the last point	“The ST_EndPoint() function” on page 8-36
	Returns the <i>n</i> th point	“The ST_PointN() function” on page 8-95
	Returns the length	“The ST_Length() function” on page 8-63
	Creates an ST_Polygon from a ring (closed linestring)	“The ST_Polygon() function” on page 8-100
Manipulate the ST_Polygon and ST_MultiPolygon data types.	Calculates the area	“The ST_Area() function” on page 8-9
	Calculates the geometric center	“The ST_Centroid() function” on page 8-21
	Returns the exterior ring	“The ST_ExteriorRing() function” on page 8-43
	Counts the number of interior rings	“The ST_NumInteriorRing() function” on page 8-85
	Returns the <i>n</i> th interior ring	“The ST_InteriorRingN() function” on page 8-52
	Returns a point on the surface	“The ST_PointOnSurface() function” on page 8-96
	Returns the perimeter	“The ST_Perimeter() function” on page 8-89

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Obtain parameters of a geometry.	Returns the dimensions of the coordinates	"The ST_CoordDim() function" on page 8-24
	Returns the dimension of the geometry	"The ST_Dimension() function" on page 8-32
	Returns the shortest distance to another geometry	"The ST_Distance() function" on page 8-35
	Returns the distance to a point	"The ST_DistanceToPoint() function" on page 8-36
	Returns the point at a specific distance	"The ST_PointAtDistance() function" on page 8-91
	Returns the data type	"The ST_GeometryType() function" on page 8-45
	Returns the number of points	"The ST_NumPoints() function" on page 8-86
	Returns the spatial reference ID	"The ST_SRID() function" on page 8-104
	Returns the maximum and minimum X coordinate	"The ST_MaxX() and ST_MinX() functions" on page 8-70
	Returns the maximum and minimum Y coordinate	"The ST_MaxY() and ST_MinY() functions" on page 8-71
	Returns the maximum and minimum Z coordinate	"The ST_MaxZ() and ST_MinZ() functions" on page 8-71
	Returns the maximum and minimum measure value	"The ST_MaxM() and ST_MinM() functions" on page 8-70
	Determine the properties of a geometry.	Determines whether a linestring or multilinestring is closed
Determines whether a geometry is empty (it has no points)		"The ST_IsEmpty() function" on page 8-59
Determines whether a geometry has measures		"The ST_IsMeasured() function" on page 8-60
Determines whether a linestring is a ring (it is closed and simple)		"The ST_IsRing() function" on page 8-61
Determines whether a geometry is simple		"The ST_IsSimple() function" on page 8-62
Determines whether a geometry is topologically valid		"The ST_IsValid() function" on page 8-63
Determines whether an object has Z coordinates		"The ST_Is3D() function" on page 8-57
Tests whether two geometries meet the conditions specified by a specified DE-91M pattern matrix		"The ST_Relate() function" on page 8-101

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Determine whether a certain relationship exists between two geometries.	Determines whether one geometry completely contains another	"The ST_Contains() function" on page 8-22
	Determines whether a geometry crosses another	"The ST_Crosses() function" on page 8-29
	Determines whether two geometries are non-intersecting	"The ST_Disjoint() function" on page 8-33
	Determines whether the envelopes of two geometries intersect	"The SE_EnvelopesIntersect() function" on page 8-41
	Determines whether two geometries are spatially equal	"The ST_Equals() function" on page 8-42
	Determines whether two geometries intersect	"The ST_Intersects() function" on page 8-56
	Determines whether two geometries overlap	"The ST_Overlaps() function" on page 8-87
	Determines whether two geometries touch	"The ST_Touches() function" on page 8-108
	Determines whether one object is completely inside another	"The ST_Within() function" on page 8-113
Compare geometries and return a new geometry based on how the geometries are related.	An aggregate function that computes the union of geometries of the same dimension	"The SE_Dissolve() function" on page 8-34
	Returns the portion of the primary geometry that is not intersected by the secondary geometry	"The ST_Difference() function" on page 8-31
	Computes the intersection of two geometries	"The ST_Intersection() function" on page 8-54
	Returns the perpendicular projection of a point on the nearest segment of a linestring	"The SE_PerpendicularPoint() function" on page 8-90
	Returns an ST_Geometry object that is composed of the parts of the two source geometries that are not common to both	"The ST_SymDifference() function" on page 8-106
	Computes the union of two geometries	"The ST_Union() function" on page 8-111

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Generate a new geometry from an existing geometry.	Generates a geometry that is the buffer that surrounds the source object	"The ST_Buffer() function" on page 8-19
	Generates the combined boundary of the geometry	"The ST_Boundary() function" on page 8-17
	Calculates the spatial extent of all geometries in a table column	"The SE_BoundingBox() function" on page 8-18
	Generates the convex hull of a geometry	"The ST_ConvexHull() function" on page 8-23
	Generates the bounding box of a geometry	"The ST_Envelope() function" on page 8-37
	Generates a geometry with fewer vertices but of the same general shape	"The SE_Generalize() function" on page 8-44
	Generates an ST_MultiPoint representing points that have the specified measure value	"The ST_LocateAlong() function" on page 8-68
	Generates an ST_MultiPoint or ST_MultiLineString representing points or paths that have measures in the specified range	"The ST_LocateBetween() function" on page 8-69
	Appends a vertex to a linestring	"The SE_VertexAppend() function" on page 8-112
	Deletes a vertex from a geometry	"The SE_VertexDelete() function" on page 8-113
	Updates a vertex in a geometry	"The SE_VertexUpdate() function" on page 8-113
Manage collections.	Returns the <i>n</i> th geometry	"The ST_GeometryN() function" on page 8-45
	Returns the number of geometries in the collection	"The ST_NumGeometries() function" on page 8-85
Nearest-neighbor queries.	Retrieves nearby geometries in increasing distance order. SE_NearestBbox() is similar to SE_Nearest() , but measures distances between bounding boxes of geometries.	"The SE_Nearest() and SE_NearestBbox() functions" on page 8-83
Assist in managing spatial reference systems.	Computes the false origin and system units for a data set and creates an entry in the spatial_references table	"The SE_CreateSRID() function" on page 8-25
	Returns the OGC well-known text representation of a spatial reference system	"The SE_CreateSrtxt() function" on page 8-27
	Returns the text for all types of spatial reference systems that use the specified ID	"The SE_CreateSrtxtList() function" on page 8-29
	Returns the number of spatial reference system types for a specified ID	"The SE_CreateSrtxtCount() function" on page 8-28
	Returns the spatial reference ID for a geometry	"The ST_SRID() function" on page 8-104
	Returns the Authority Name and Authority SRID of a spatial reference ID	"The SE_SRID_Authority() function" on page 8-105
	Transforms a geometry from one spatial reference system to another	"The ST_Transform() function" on page 8-109

Table 8-2. Spatial functions by task type (continued)

Function task type	Description	Function name
Administration	Returns the in-row, out-of-row, and total size of a geometry in bytes	“The SE_InRowSize() function” on page 8-52 “The SE_OutOfRowSize() function” on page 8-87 “The SE_TotalSize() function” on page 8-107
	Reinitializes the spatial reference system memory cache	“The SE_MetadataInit() function” on page 8-71
	Returns the value of a specified parameter or all parameters if called with no parameters	“The SE_ParamGet() function” on page 8-88
	Sets the specified parameter to a new value	“The SE_ParamSet() function” on page 8-89
	Returns usage information (if called with no parameters)	“The SE_ParamSet() function” on page 8-89
	Returns the version and release date of the spatial data extension	“The SE_Release() function” on page 8-102
	Generates a sort key for geometries	“The SE_SpatialKey() function” on page 8-103
	Controls tracing to assist in debugging	“The SE_Trace() function” on page 8-108

The ST_Area() function

The `ST_Area()` function returns the area of a polygon or multipolygon.

Syntax

```
ST_Area(p11 ST_Polygon)
ST_Area(mp11 ST_MultiPolygon)
```

Return type

DOUBLE PRECISION

Example

The city engineer needs a list of building areas. To create the list, a GIS technician selects the building ID and area of each building footprint.

The building footprints are stored in the **buildingfootprints** table created with the following CREATE TABLE statement:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);
```

To satisfy the city engineer's request, the technician selects the unique key, the **building_id**, and the **area** of each building footprint from the **buildingfootprints** table:

```
SELECT building_id, ST_Area(footprint) area
FROM buildingfootprints;
```

building_id	area
506	78.000000000000
543	68.000000000000
1208	123.000000000000
178	87.000000000000

The following figure shows the four building footprints labeled with their building ID numbers and displayed alongside their adjacent street.

Figure 8-1. Building footprints

The ST_AsBinary() function

The **ST_AsBinary()** function takes a geometry object and returns its well-known binary representation.

The return type of **ST_AsBinary()** is defined as **ST_Geometry** to allow spatial objects greater than 2 kilobytes to be retrieved by a client application. Typically, you use **ST_AsBinary()** to retrieve spatial data from the server and send it to a client, as in:

```
SELECT ST_AsBinary(geomcol) FROM mytable
```

IBM Informix automatically casts the output of the **ST_AsBinary()** function to the proper data type for transmission to the client.

You can write user-defined routines (UDRs) in C or SPL to extend the functionality of the existing spatial data type functions. You can use **ST_AsBinary()** to convert an **ST_Geometry** to its well-known binary representation. If you pass the output of **ST_AsBinary()** to another UDR whose function signature requires an **LVARCHAR** input, you should explicitly cast the return type of **ST_AsBinary()** to **LVARCHAR**, as in:

```
EXECUTE FUNCTION MySpatialFunc(ST_AsBinary(geomcol)::lvarchar);
```

Syntax

```
ST_AsBinary(g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The code fragment below converts the footprint multipolygons of the **buildingfootprints** table into WKB multipolygons using the **ST_AsBinary()** function. The multipolygons are passed to the application's **draw_polygon()** function for display:

```
/* Create the SQL expression. */
sprintf(sql_stmt,
        "SELECT ST_AsBinary(zone) "
        "FROM sensitive_areas WHERE "
        "SE_EnvelopesIntersect(zone,ST_PolyFromWKB(?,%d))", srid);

/* Prepare the SQL statement. */
SQLPrepare(hstmt, (UCHAR *) sql_stmt, SQL_NTS);

/* Bind the query shape parameter. */
pcbvalue1 = query_wkb_len;
SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_BINARY,
                  SQL_INFX_UDT_LVARCHAR, query_wkb_len, 0,
                  query_wkb_buf, query_wkb_len, &pcbvalue1);

/* Execute the query. */
rc = SQLExecute(hstmt);

/* Assign the results of the query (the buildingfootprint polygons)
 * to the fetched_binary variable. */
SQLBindCol (hstmt, 1, SQL_C_BINARY,
            fetched_wkb_buf, 10000, &fetched_wkb_len);

/* Fetch each polygon within the display window and display it. */
while (1)
{
    rc = SQLFetch(hstmt);
    if (rc == SQL_NO_DATA_FOUND)
        break;
    else
        returncode_check(NULL, hstmt, rc, "SQLFetch");

    draw_polygon(fetched_wkb_buf);
}

/* Close the result set cursor */
SQLCloseCursor(hstmt);
```

The SE_AsGML() function

The **SE_AsGML()** function returns the Geography Markup Language (GML) representation of an **ST_Geometry** spatial type.

Typically, you use the **SE_AsGML()** function to retrieve the GML representation of a spatial primitive from the server and send it to a client, as in:

```
SELECT SE_AsGML(geomcol) FROM mytable
```

The return type of the **SE_AsGML()** function is defined as **LVARCHAR**. You can write user-defined routines (UDRs) in C or SPL to extend the functionality of the existing spatial data type functions. You can use the **SE_AsGML()** function to convert an **ST_Geometry** type to its GML representation.

Syntax

```
SE_AsGML(p ST_Geometry)
```

Return type

ST_Geometry

Example

In this example, the **SE_AsGML()** function converts the **location** column of the table **mytable** into its GML description.

```
CREATE TABLE mytable (id integer, location ST_Point);

INSERT INTO mytable VALUES(
    1,
    ST_PointFromText('point (10.02 20.01)', 1000)
);

SELECT SE_AsGML(location) FROM mytable WHERE id = 1;

<gml:Point srsName="UNKNOWN">
<gml:coord><gml:X>10.02</gml:X><gml:Y>20.01</gml:Y></gml:coord>
</gml:Point>
```

The `$INFORMIXDIR/extend/spatial.version/examples/gml` directory contains more information about how to use an XML parser to validate the results of this function.

The ST_AsGML() function

The **ST_AsGML()** function returns the Geography Markup Language (GML) representation of an ST_Geometry spatial type that conforms to either the GML2 or GML3 standard.

Typically, you use the **ST_AsGML()** function to retrieve the GML representation of a spatial primitive from the server and send it to a client, specifying the GML version to use. For example:

```
SELECT ST_AsGML(geomcol, 3) FROM mytable
```

Syntax

```
ST_AsGML(p ST_Geometry, int Version)
```

Version is the GML version that is used to encode the returned geometry. Specify 2 for GML2 and 3 for GML3. The default is 2.

Return type

ST_Geometry

Example

The first example returns a geometry from the **mypoints** table as a GML2 representation. The second example returns the geometry as a GML3 representation.

```
SELECT id, ST_AsGML(pt,2) FROM mypoints WHERE id=1

id 1
<gml:Point> <gml:coord><gml:X>-95.7</gml:X>
<gml:Y>38.1</gml:Y></gml:coord></gml:Point>

SELECT id, ST_AsGML(pt,3) AS gml_v32arg, ST_AsGML(pt)
```

```

AS gml_v31arg FROM mypoints WHERE id=1

id 1
gml_v32arg <gml:Point><gml:pos>-95.7 38.1</gml:pos></gml:Point>
gml_v31arg <gml:Point><gml:pos>-95.7 38.1</gml:pos></gml:Point>

```

The `$INFORMIXDIR/extend/spatial.version/examples/gml` directory contains more information about how to use an XML parser to validate the results of this function.

The SE_AskML() function

The **SE_AskML()** function returns the Keyhole Markup Language (KML) representation of an `ST_Geometry` spatial type.

Typically, you use the **SE_AskML()** function to retrieve the KML representation of a spatial primitive from the server and send it to a client, as in:

```
SELECT SE_AskML(geomcol) FROM mytable
```

The return type of the **SE_AskML()** function is defined as `LVARCHAR`. You can write user-defined routines (UDRs) in C or SPL to extend the functionality of the existing spatial data type functions.

Syntax

```
SE_AskML(p ST_Geometry)
```

Return type

`ST_Geometry`

Example

In this example, the **SE_AskML()** function converts the **location** column of the table **mytable** into its KML description.

```

CREATE TABLE mytable (id integer, location ST_Point);

INSERT INTO mytable VALUES(
  1, ST_PointFromText('point (10.02 20.01)', 1000)
);

SELECT id, SE_AskML(p1) FROM point_t ORDER BY id asc;
id      100_xy
<Point><coordinates>10.02,20.01</coordinates></Point>

CREATE TABLE line_t (id integer, p1 ST_LineString);

INSERT INTO line_t VALUES(
  1,
  ST_LineFromText('linestring (0.0 0.0,0.0 1.0,1.0 0.0,1.0 1.0)',1000)
);
1 row(s) inserted.

INSERT INTO line_t VALUES(
  2,
  ST_LineFromText('linestring z (0.0 0.0 0,0.0 1.0 1,1.0 0.0 1,1.0 1.0 1)',1000)
);
1 row(s) inserted.

INSERT INTO line_t VALUES(

```

```

3,
ST_LineFromText('linestring m (0.0 0.0 0,0.0 1.0 1,1.0 0.0 1,1.0 1.0 1)',1000)
);
1 row(s) inserted.

```

```

SELECT id, SE_AsKML(p1) FROM line_t ORDER BY id ASC;

id          2
<LineString>
  <coordinates>0,0,0 0,1,1 1,0,1 1,1,1</coordinates>
</LineString>
id          3
<LineString><coordinates>0,0 0,1 1,0 1,1</coordinates></LineString>

```

The ST_AsKML() function

The **ST_AsKML()** function returns the Keyhole Markup Language (KML) representation of an **ST_Geometry** spatial type.

ST_AsKML() can also take an optional parameter that describes KML shape attributes.

Syntax

```

ST_AsKML(p ST_Geometry)
ST_AsKML(p ST_Geometry, attributes lvarchar)

```

The attributes parameter can contain one or more KML shape attributes, in XML format. The following table describes common KML shape attributes.

Table 8-3. KML shape attributes

Attribute	Description
<extrude>	<p>A Boolean value that specifies if the geometry is connected to the ground (1) or not (0). To extrude a geometry, the value of the <altitudeMode> attribute must be either relativeToGround or absolute and the Z coordinate within the <coordinates> element must be greater than zero (0).</p> <p>If this attribute is not specified, it is false (0).</p>
<tessellate>	<p>A Boolean value that specifies if the geometry should follow the terrain (1) or not (0). To enable tessellation for the geometry, the value for the <altitudeMode> attribute must be clampToGround.</p> <p>If this attribute is not specified, it is false (0).</p>
<altitudeMode>	<p>Specifies how Z coordinates in the <coordinates> element are interpreted. Possible values are:</p> <p>clampToGround (default) Indicates to ignore the altitude specification in the geometry and place it at ground level.</p> <p>relativeToGround Interprets the altitude specification in the geometry and places it at that altitude above the ground.</p> <p>absolute Interprets the altitude specification in the geometry and places it at that altitude above sea level.</p>

The Spatial DataBlade module does not check whether the attributes are valid. If any of the attributes are not valid, the resulting KML fragment might not be valid when it is received by the application.

Return type

LVARCHAR

Example

```
EXECUTE FUNCTION ST_AsKML(ST_PointFromText('POINT(-83.54354 34.23425)',4))
```

Output:

```
<Point>
  <coordinates>-83.5435399663,34.2342500677</coordinates>
</Point>
```

In this example, **ST_AsKML()** contains KML shape attributes to specify that the geometry is connected to the ground:

```
EXECUTE FUNCTION ST_AsKML(ST_PointFromText('POINT Z
(-83.54523 34.214312 100)',4),
  '<extrude>1</extrude><altitudeMode>
  clampToGround</altitudeMode>');
```

Output:

```
<Point>
  <extrude>1</extrude>
  <altitudeMode>clampToGround</altitudeMode>
  <coordinates>-83.545522957,34.2143120335,100</coordinates>
</Point>
```

The SE_AsShape() function

The **SE_AsShape()** function takes a geometry object and returns it in ESRI shapefile format.

The return type of **SE_AsShape()** is defined as **ST_Geometry** to allow spatial objects greater than 2 kilobytes in size to be retrieved by a client application.

Typically, you use **ST_AsShape()** to retrieve spatial data from the server and send it to a client, as in:

```
SELECT SE_AsShape(geomcol) FROM mytable
```

IBM Informix automatically casts the output of the **SE_AsShape()** function to the proper data type for transmission to the client.

You can write user-defined routines (UDRs) in C or SPL to extend the functionality of the existing spatial data type functions. You can use **SE_AsShape()** to convert an **ST_Geometry** to ESRI shapefile format. If you pass the output of **SE_AsShape()** to another UDR whose function signature requires an **LVARCHAR** input, you should explicitly cast the return type of **SE_AsShape()** to **LVARCHAR**, as in:

```
EXECUTE FUNCTION MySpatialFunc(SE_AsShape(geomcol)::lvarchar);
```

Syntax

```
SE_AsShape(g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The code fragment below illustrates how the **SE_AsShape()** function converts the **zone** polygons of the **sensitive_areas** table into shape polygons. These shape polygons are passed to the application's **draw_polygon()** function for display:

```
/* Create the SQL expression. */
sprintf(sql_stmt,
        "SELECT SE_AsShape(zone) "
        "FROM sensitive_areas WHERE "
        "SE_EnvelopesIntersect(zone,SE_PolyFromShape(?,%d)", srid);

/* Prepare the SQL statement. */
SQLPrepare(hstmt, (UCHAR *)sql_stmt, SQL_NTS);

/* Bind the query geometry parameter. */
pcbvalue1 = query_shape_len;
SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_BINARY,
                  SQL_INFX_UDT_LVARCHAR, query_shape_len, 0,
                  query_shape_buf, query_shape_len, &pcbvalue1);

/* Execute the query. */
rc = SQLExecute(hstmt);

/* Assign the results of the query (the Zone polygons) to the
   fetched_shape_buf variable. */
SQLBindCol (hstmt, 1, SQL_C_BINARY,
            fetched_shape_buf, 10000, &fetched_shape_len);

/* Fetch each polygon within the display window and display it. */
while (SQL_SUCCESS == (rc = SQLFetch(hstmt)))
    draw_polygon(fetched_shape_buf);
```

The ST_AsText() function

The **ST_AsText()** function takes an **ST_Geometry** object and returns its well-known text representation.

The return type of **ST_AsText()** is defined as **ST_Geometry** to allow spatial objects greater than 2 kilobytes to be retrieved by a client application.

Typically, you use **ST_AsText()** to retrieve spatial data from the server and send it to a client, as in:

```
SELECT ST_AsText(geomcol) FROM mytable
```

IBM Informix automatically casts the output of the **ST_AsText()** function to the proper data type for transmission to the client.

You can write user-defined routines (UDRs) in C or SPL to extend the functionality of the existing spatial data type functions. You can use **ST_AsText()** to convert an **ST_Geometry** to its well-known text representation. If you pass the output of **ST_AsText()** to another UDR whose function signature requires an **LVARCHAR** input, you should explicitly cast the return type of **ST_AsText()** to **LVARCHAR**, as in:

```
EXECUTE FUNCTION MySpatialFunc(ST_AsText(geomcol)::lvarchar)
```

Syntax

```
ST_AsText(g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The `ST_AsText()` function converts the `hazardous_sites` location point into its text description:

```
CREATE TABLE hazardous_sites (site_id integer,
                                name varchar(40),
                                location ST_Point);
```

```
INSERT INTO hazardous_sites VALUES(
    102, 'W. H. Kleenare Chemical Repository',
    ST_PointFromText('point (1020.12 324.02)',1000)
);
SELECT site_id, name, ST_AsText(location) Location
FROM hazardous_sites;
```

```
site_id  102
name     W. H. Kleenare Chemical Repository
location POINT (1020.12 324.02)
```

The `ST_Boundary()` function

The `ST_Boundary()` function takes a geometry object and returns its combined boundary as a geometry object.

Syntax

```
ST_Boundary(g1 ST_Geometry)
```

Return type

ST_Geometry

Example

In this example the `boundary_test` table is created with two columns: `geotype` defined as a `VARCHAR`, and `g1` defined as the superclass `ST_Geometry`. The `INSERT` statements that follow insert each one of the subclass geometries. The `ST_Boundary()` function retrieves the boundary of each subclass stored in the `g1` geometry column. Note that the dimension of the resulting geometry is always one less than the input geometry. Points and multipoints always result in a boundary that is an empty geometry, dimension -1. Linestrings and multilinestrings return a multipoint boundary, dimension 0. A polygon or multipolygon always returns a multilinestring boundary, dimension 1:

```
CREATE TABLE boundary_test (geotype varchar(20),
                              g1 ST_Geometry);
```

```
INSERT INTO boundary_test VALUES(
    'Point', ST_PointFromText('point (10.02 20.01)',1000)
);
```

```

INSERT INTO boundary_test VALUES(
  'Linestring',
  ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO boundary_test VALUES(
  'Polygon',
  ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02 34.15,19.15
33.94, 10.02 20.01))',1000)
);

INSERT INTO boundary_test VALUES(
  'Multipoint',
  ST_MPointFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO boundary_test VALUES(
  'Multilinestring',
  ST_MLineFromText('multilinestring ((10.02 20.01,10.32 23.98,11.92 25.64),
(9.55 23.75,15.36 30.11))',1000)
);

INSERT INTO boundary_test VALUES(
  'Multipolygon',
  ST_MPolyFromText('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52 32.87,52.43
31.90,51.71 21.73)))',1000)
);

SELECT geotype, ST_Boundary(g1)
FROM boundary_test;

```

```

geotype      Point
(expression) 1000 POINT EMPTY

geotype      Linestring
(expression) 1000 MULTIPOINT (10.02 20.01, 11.92 25.64)

geotype      Polygon
(expression) 1000 MULTILINESTRING ((10.02 20.01, 19.15 33.94, 25.02
34.15, 11.92 35.64, 10.02 20.01))

geotype      Multipoint
(expression) 1000 POINT EMPTY

geotype      Multilinestring
(expression) 1000 MULTIPOINT (9.55 23.75, 10.02 20.01, 11.92 25.64, 15.36 30.1
1)

geotype      Multipolygon
(expression) 1000 MULTILINESTRING ((10.02 20.01, 19.15 33.94, 25.02 34.15,
11.92 35.64, 10.02 20.01),(51.71 21.73, 73.36 27.04, 71.52 32.87, 52.43
31.9, 51.71 21.73))

```

The SE_BoundingBox() function

The **SE_BoundingBox()** function returns a polygon which represents the spatial extent (the minimum and maximum X and Y values) of all the geometries in a spatial column of a table.

Important: You must have an R-tree index on the spatial column.

Syntax

```
SE_BoundingBox (tablename varchar(128),  
                columnname varchar(128))
```

Return type

ST_Polygon

Example

The **buildingfootprints** table is created with the following statement. The **building_id** column uniquely identifies the buildings, the **lot_id** identifies the building's lot, and the footprint multipolygon stores the building's geometry:

```
CREATE TABLE buildingfootprints (building_id integer,  
                                lot_id integer,  
                                footprint ST_MultiPolygon);
```

After the table is populated, create an R-tree index on the **footprint** column:

```
CREATE INDEX footprint_idx  
  ON buildingfootprints (footprint ST_Geometry_ops)  
  USING RTREE;
```

Use the **SE_BoundingBox()** function to obtain a polygon that defines the spatial extent of all the polygons in the table:

```
EXECUTE FUNCTION SE_BoundingBox ('buildingfootprints', 'footprint');
```

```
(expression) 1000 POLYGON ((7 22, 38 22, 38 55, 7 55, 7 22))
```

Obtaining the Spatial Extent of a Functional Index

You cannot use the **SE_BoundingBox()** function on a functional R-tree index. Instead, you must use the **rtreeRootBB()** function. The **rtreeRootBB()** function takes the index name and type name as arguments and returns the well-known text representation of an ST_Polygon, as shown in the following example:

```
CREATE TABLE xytab (x float, y float, srid int);  
  
INSERT INTO xytab VALUES (1, 2, 0);  
INSERT INTO xytab VALUES (3, 4, 0);  
  
CREATE INDEX point_idx ON xytab  
  (ST_Point(x,y,srid) ST_Geometry_ops) USING RTREE;  
  
EXECUTE FUNCTION rtreeRootBB('point_idx', 'st_point');  
  
(expression) 0 POLYGON ((1 2, 3 2, 3 4, 1 4, 1 2))
```

See also

“The ST_Envelope() function” on page 8-37

The ST_Buffer() function

The **ST_Buffer()** function takes a geometry object and distance and returns a geometry object that is the buffer surrounding the source object.

Syntax

```
ST_Buffer(g1 ST_Geometry, distance double_precision)
```

Return type

ST_Geometry

Example

The county supervisor needs a list of hazardous sites whose five-mile radius overlaps sensitive areas such as schools, hospitals, and nursing homes. The sensitive areas are stored in the table **sensitive_areas** that is created with the CREATE TABLE statement shown below. The **zone** column, defined as a **ST_Polygon**, stores the outline of each of the sensitive areas:

```
CREATE TABLE sensitive_areas (id      integer,
                               name    varchar(128),
                               size    float,
                               type    varchar(10),
                               zone    ST_Polygon);
```

The hazardous sites are stored in the following **hazardous_sites** table. The **location** column, defined as a point, stores the geographic center of each hazardous site:

```
CREATE TABLE hazardous_sites (site_id integer,
                                name     varchar(40),
                                location  ST_Point);
```

The **sensitive_areas** and **hazardous_sites** tables are joined by the **ST_Overlaps()** function, which returns t (TRUE) for all **sensitive_areas** rows whose **zone** polygons overlap the buffered five-mile radius of the **hazardous_sites** location point.

```
SELECT sa.name, hs.name
       FROM sensitive_areas sa, hazardous_sites hs
       WHERE ST_Overlaps(sa.zone, ST_Buffer(hs.location,26400));
```

```
name Johnson County Hospital
name Landmark Industrial
```

```
name Summerhill Elementary School
name Landmark Industrial
```

The following figure shows that some of the sensitive areas in this administrative district lie within the five-mile buffer radius of the hazardous site locations. It is clear that both buffers intersect the hospital and one intersects the school. The nursing home lies safely outside both radii.

Figure 8-2. Sensitive areas

“The ST_Buffer function” on page 7-12

The ST_Centroid() function

The **ST_Centroid()** function takes a polygon or multipolygon and returns its geometric center as a point.

Syntax

```
ST_Centroid(p11 ST_Polygon)
ST_Centroid(mp11 ST_MultiPolygon)
```

Return type

ST_Point

Example

The city GIS technician wants to display the building footprint multipolygons as single points in a building density graphic.

The building footprints are stored in the **buildingfootprints** table that was created with the following CREATE TABLE statement:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);
```

The **ST_Centroid()** function returns the centroid of each building footprint multipolygon:

```
SELECT building_id, ST_Centroid(footprint) Centroid
FROM buildingfootprints;
```

```
building_id 506
centroid    1000 POINT (12.5 49.5)
```

```

building_id 543
centroid    1000 POINT (32 51.5)

building_id 1208
centroid    1000 POINT (12.5 30.5)

building_id 178
centroid    1000 POINT (32 28.5)

```

The ST_Contains() function

The **ST_Contains()** function takes two geometry objects and returns t (TRUE) if the first object completely contains the second; otherwise, it returns f (FALSE).

Syntax

```
ST_Contains(g1 geometry, g2 geometry)
```

Return type

BOOLEAN

Example

In the example below, two tables are created: **buildingfootprints** contains a city's building footprints, and **lots** contains its lots. The city engineer wants to ensure that all building footprints are completely inside their lots.

In both tables, the ST_MultiPolygon data type stores the geometry of the building footprints and the lots. The database designer selected multipolygons for both features because lots can be separated by natural features such as a river, and building footprints can comprise several buildings:

```

CREATE TABLE buildingfootprints (building_id integer,
                                lot_id       integer,
                                footprint    ST_MultiPolygon);

CREATE TABLE lots (lot_id integer,
                   lot     ST_MultiPolygon);

```

The city engineer first selects the buildings that are not completely contained within one lot:

```

SELECT building_id
FROM buildingfootprints, lots
WHERE NOT ST_Contains(lot,footprint);

```

The city engineer realizes that although the first query provides a list of all building IDs that have footprints outside a lot polygon, it will not tell if the rest have the correct **lot_id** assigned to them. This second query performs a data integrity check on the **lot_id** column of the **buildingfootprints** table:

```

SELECT bf.building_id, bf.lot_id, lots.lot_id
FROM buildingfootprints bf, lots
WHERE NOT ST_Contains(lot,footprint)
AND lots.lot_id <> bf.lot_id;

```

In the following figure, the building footprints are labeled with their building IDs and lie inside their lot lines. The lot lines are illustrated with dotted lines and, although not shown, extend to the street centerline to completely encompass the lot lines and the building footprints within them.

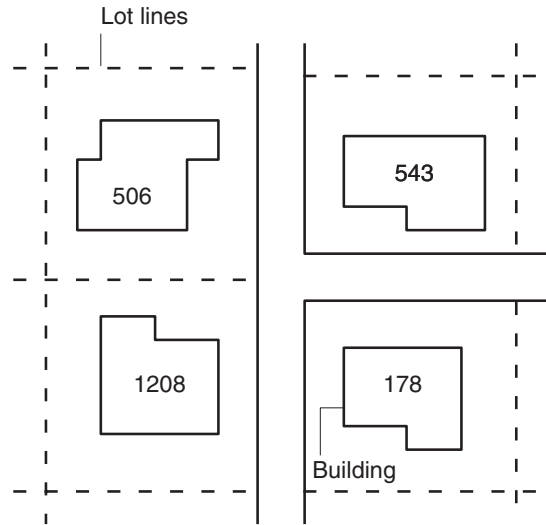

Figure 8-3. Building footprints and lot lines.

“The ST_Contains() function” on page 7-21

The ST_ConvexHull() function

The ST_ConvexHull() function returns the convex hull of a geometry object.

Syntax

```
ST_ConvexHull (g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The example creates the **convexhull_test** table that has two columns: **geotype** and **g1**. The **geotype** column is of VARCHAR(20) type and holds the name of the geometry subclass that is stored in **g1**, an ST_Geometry column:

```
CREATE TABLE convexhull_test (geotype varchar(20),
                               g1 ST_Geometry);
```

The following INSERT statements insert several geometry subclasses into the **convexhull_test** table:

```
INSERT INTO convexhull_test VALUES(
    'Point',
    ST_PointFromText('point (10.02 20.01)',1000)
);
```

```
INSERT INTO convexhull_test VALUES(
    'Linestring',
    ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);
```

```
INSERT INTO convexhull_test VALUES(
    'Polygon',
    ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02 34.15,
```

```

19.15 33.94,10.02 20.01))',1000)
);

INSERT INTO convexhull_test VALUES(
  'MultiPoint',
  ST_MPointFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO convexhull_test VALUES(
  'MultiLineString',
  ST_MLineFromText('multilinestring ((10.02 20.01,10.32 23.98,11.92
25.64),(9.55 23.75,15.36 30.11))',1000)
);

INSERT INTO convexhull_test VALUES(
  'Multipolygon',
  ST_MPolyFromText('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52
32.87,52.43 31.90,51.71 21.73)))',1000)
);

```

The SELECT statement lists the subclass name stored in the **geotype** column and the convex hull:

```

SELECT geotype, ST_ConvexHull(g1) convexhull
FROM convexhull_test;

```

Related reference:

“The ST_ConvexHull() function” on page 7-14

The ST_CoordDim() function

The **ST_CoordDim()** function returns the coordinate dimensions of the ST_Geometry value.

For example, a point with a Z coordinate has three dimensions and a point with a Z coordinate and measures has four dimensions.

Syntax

```

ST_CoordDim(g ST_Geometry)

```

Return type

INTEGER

Example

The **coorddim_test** table is created with the columns **geotype** and **g1**. The **geotype** column stores the name of the geometry subclass stored in the **g1** ST_Geometry column:

```

CREATE TABLE coorddim_test (geotype varchar(20),
                             g1      ST_Geometry);

```

The INSERT statements insert a sample subclass into the **coorddim_test** table:

```

INSERT INTO coorddim_test VALUES(
  'Point',
  ST_PointFromText('point (10.02 20.01)',1000)
);

INSERT INTO coorddim_test VALUES(
  'Point',

```

```

    ST_PointFromText('point z (10.02 20.01 3.21)',1000)
);

INSERT INTO coorddim_test VALUES(
    'LineString',
    ST_LineFromText('linestring (10.02 20.01, 10.32 23.98, 11.92 25.64)',1000)
);

INSERT INTO coorddim_test VALUES(
    'LineString',
    ST_LineFromText('linestring m (10.02 20.01 1.23, 10.32 23.98 4.56, 11.92
25.64 7.89)',1000)
);

INSERT INTO coorddim_test VALUES(
    'Polygon',
    ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94, 10.02 20.01))',1000)
);

INSERT INTO coorddim_test VALUES(
    'Polygon',
    ST_PolyFromText('polygon zm ((10.02 20.01 9.87 1.23, 11.92
35.64 7.65 2.34, 25.02 34.15 6.54 3.45, 19.15 33.94 5.43 4.56,
10.02 20.01 9.87 1.23))',1000)
);

```

The SELECT statement lists the subclass name stored in the **geotype** column with the dimension of that geometry:

```

SELECT geotype, ST_CoordDim(g1) coord_dimension
FROM coorddim_test;

```

geotype	coord_dimension

The SE_CreateSRID() function

The **SE_CreateSRID()** function is a utility function that, given the X and Y extents of a spatial data set, computes the false origin and system units and creates a new entry in the **spatial_references** table. Appropriate offsets and scale factors for typical Z values and M values are also provided.

The **spatial_references** table holds data about spatial reference systems. A spatial reference system is a description of a coordinate system for a set of geometric objects; it gives meaning to the X and Y values that are stored in the database.

You need to specify an SRID of a spatial reference system when you load spatial data into a database, because the database server translates and scales each floating point coordinate of the geometry into a 53-bit positive integer prior to storage.

The **spatial_references** table is pre-loaded with an entry for SRID=0, which is suitable for worldwide spatial data in latitude/longitude format.

If SRID=0 is not suitable for your data, you can use **SE_CreateSRID()** to assist you in creating a more appropriate **spatial_references** table entry. However, because the **SE_CreateSRID()** function only considers the X and Y extents of your data, it may not create sufficiently refined parameters to describe the spatial reference system you need. For more information about spatial reference systems and how to compute false origins and scale factors, review “The spatial_references table” on page 1-5.

Syntax

```
SE_CreateSrid (xmin float, ymin float,  
              xmax float, ymax float,  
              description varchar(64))
```

The *description* parameter is provided to encourage you to document any SRIDs that you create with this function.

Return type

Returns the SRID of a newly created **spatial_references** table entry as an integer

If the **spatial_references** table already contains an identical entry, its SRID is returned.

Example

To create an entry in the **spatial_references** table that is suitable for spatial data in New Zealand:

```
EXECUTE FUNCTION SE_CreateSrid (166, -48, 180, -34,  
                               "New Zealand: lat/lon coords");
```

(expression)

1001

The following query shows the resulting **spatial_references** table entry:

```
SELECT * FROM spatial_references WHERE srid = 1001;
```

srid	1001
description	New Zealand: lat/lon coords
auth_name	
auth_srid	
falsex	164.6000000000
falsey	-49.4000000000
xyunits	127826407.5600
falsez	-1000.00000000
zunits	1000.00000000
falsem	-1000.00000000
munits	1000.00000000
srttext	UNKNOWN

See also

“The SE_CreateSrttext() function” on page 8-27

Related concepts:

“Select a false origin and system units” on page 1-6

Related reference:

“The SE_CreateSrttext() function”

The SE_CreateSrttext() function

The **SE_CreateSrttext()** function returns the OGC well-known text representation of a spatial reference system, given the ESRI Projection Engine ID number for a coordinate system.

The ID numbers are in the file `pedef.h`, in the directory `$INFORMIXDIR/extend/spatial.version/include`.

Syntax

`SE_CreateSrttext (factory_id integer)`

`SE_CreateSrttext (factory_id integer, type varchar(64) default NULL)`

The *type* parameter indicates the type of spatial reference system when different types of systems have overlapping IDs. The following table lists the values of the *type* parameter. You can use either the long type value or the corresponding short type value.

Table 8-4. Object types

Long type value	Short type value	Spatial reference system name
geogcs	gcs	Geographic Coordinate System
projcs	pcs	Projected Coordinate System
coordsys	crs	Either the Geographic Coordinate System or the Project Coordinate System
vertcs	vcs	Vertical Coordinate System
geoxyzcs	xyz	Geographic Coordinate System with XYZ coordinates
hvcoordsys	hvc	Horizontal-vertical Coordinate System
datum	dat	Datum
vdatum	vdt	Vertical datum
hvdatum	hvd	Either datum or vertical datum
geogtran	gtf	Geographic Transform
verttran	vtf	Vertical Transform
linunit	lin	Linear units
angunit	ang	Angular units
unit	uni	Either linear or angular units
areaunit	are	Area units
primem	pri	Prime Meridian

Table 8-4. Object types (continued)

Long type value	Short type value	Spatial reference system name
spheroid	sph	Spheroid
method	mth	Method
htmethod	htm	Horizontal method
vtmethod	vtm	Vertical method
projection	prj	Projection method
parameter	par	Parameter

Return type

LVARCHAR

Example

To obtain the spatial reference system text for the 1983 North American Datum:

```
EXECUTE FUNCTION SE_CreateSrtext(4269);
```

```
(expression) GEOGCS["GCS_North_American_1983",DATUM["D_North_American_1983",SPHEROID["GRS_1980",6378137,298.257222101]],PRIMEM["Greenwich",0],UNIT["Degree",0.0174532925199432955]]
```

Tip: You can transfer the output of **SE_CreateSrtext()** directly into the **spatial_references** table with the following SQL statement:

```
UPDATE spatial_references
SET srtext = SE_CreateSrtext(4269) WHERE srid = 1000;
```

Related reference:

“The SE_CreateSRID() function” on page 8-25

“The text representation of a spatial system” on page B-1

The SE_CreateSrtextCount() function

The **SE_CreateSrtextCount()** function returns the number of spatial reference systems that use the specified ESRI Projection Engine ID number.

Syntax

```
SE_CreateSrtextCount (factory_id int)
```

Return type

INTEGER

Example

To return the number of spatial reference systems that use the ID 5109:

```
EXECUTE FUNCTION SE_SrtextCount(5109);
```

```
(expression)
```

1 row(s) retrieved.

The ID 5109 has two spatial reference system types.

The SE_CreateSrtextList() function

The **SE_CreateSrtextList()** function returns the OGC well-known text representation of every spatial reference system that uses the specified ESRI Projection Engine ID number. The text for each spatial reference system is separated by a new line character.

If the specified ID number is used by a single spatial reference system, the **SE_CreateSrtextList()** function returns the same text as the **SE_CreateSrtext()** function. The ID numbers are in the file `pedef.h`, in the directory `$INFORMIXDIR/extend/spatial.version/include`.

Syntax

```
SE_CreateSrtextList (factory_id int)
```

Return type

LVARCHAR

Example

To return the spatial reference system text for the ID 5109:

```
EXECUTE FUNCTION SE_CreateSrtextList(5109);
```

```
(expression) PROJCS["ETRS_1989_NTM_Zone_9",GEOGCS["GCS_ETRS_1989",DATUM["D_ETR
S_1989",SPHEROID["GRS_1980",6378137.0,298.257222101]],PRIMEM["Gre
enwich",0.0],UNIT["Degree",0.0174532925199433]],PROJECTION["Trans
verse_Mercator"],PARAMETER["False_Easting",100000.0],PARAMETER["F
alse_Northing",1000000.0],PARAMETER["Central_Meridian",9.5],PARAM
ETER["Scale_Factor",1.0],PARAMETER["Latitude_Of_Origin",58.0],UNI
T["Meter",1.0]]
VDATUM["Normaal_Amsterdams_Peil"]
```

1 row(s) retrieved.

The ID 5109 has two spatial reference system types: a Projected Coordinate System and a vertical datum.

The ST_Crosses() function

The **ST_Crosses()** function takes two geometry objects and returns t (TRUE) if their intersection results in an ST_Geometry object whose dimension is one less than the maximum dimension of the source objects.

The intersection object must contain points that are interior to both source geometries, and the intersection object must not be equal to either of the source objects. Otherwise, it returns f (FALSE).

Syntax

```
ST_Crosses(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The county government is considering a new regulation stating that all hazardous waste storage facilities may not be within five miles of any waterway. The county GIS manager has an accurate representation of rivers and streams stored as multilinestrings in the **waterways** table, but has only a single point location for each of the hazardous waste storage facilities:

```
CREATE TABLE waterways (id      integer,
                        name    varchar(128),
                        water   ST_MultiLineString);
```

```
CREATE TABLE hazardous_sites (site_id integer,
                               name     varchar(40),
                               location  ST_Point);
```

To determine if it is necessary to alert the county supervisor to any existing facilities that would violate the proposed regulation, the GIS manager has to buffer the **hazardous_sites** locations to see if any rivers or streams cross the buffer polygons. The **ST_Crosses()** function compares the buffered **hazardous_sites** with **waterways**, returning only those records where the waterway crosses over the county's proposed regulated radius:

```
SELECT ww.name waterway, hs.name hazardous_site
FROM waterways ww, hazardous_sites hs
WHERE ST_Crosses(ST_Buffer(hs.location,(5 * 5280)),ww.water);
```

```
waterway      Fedders creek
hazardous_site Landmark Industrial
```

The following figure shows that the five-mile buffered radius of the hazardous waste sites crosses the stream network that runs through the county's administrative district. Because the stream network is defined as an **ST_MultiLineString**, all linestring segments that are part of those segments that cross the radius are included in the result set

Figure 8-4. Hazardous waste sites and the stream network.

Related reference:

“The ST_Crosses() function” on page 7-4

“The ST_Crosses() function” on page 7-20

The ST_Difference() function

The **ST_Difference()** function takes two geometry objects and returns a geometry object that is the difference of the source objects.

Syntax

```
ST_Difference(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

ST_Geometry

Example

The city engineer needs to know the total city lot area not covered by buildings. In fact, the engineer wants the sum of the lot area after the building area has been removed:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id       integer,
                                footprint    ST_MultiPolygon);
```

```
CREATE TABLE lots (lot_id integer,
                   lot     ST_MultiPolygon);
```

The city engineer equijoins the **buildingfootprints** and **lots** table on the **lot_id** column and takes the sum of the area of the difference of the lots less the building footprints:

```
SELECT SUM(ST_Area(ST_Difference(lot, footprint)::ST_MultiPolygon))
FROM buildingfootprints bf, lots
WHERE bf.lot_id = lots.lot_id;
```

Related reference:

“The ST_Difference() function” on page 7-8

The ST_Dimension() function

The **ST_Dimension()** function returns the dimension of a geometry object.

A geometry can have one of three dimensions:

- 0 The geometry has neither length nor area.
- 1 The geometry has length.
- 2 The geometry has area.

Syntax

```
ST_Dimension(g1 ST_Geometry)
```

Return type

INTEGER

Example

The **dimension_test** table is created with the columns **geotype** and **g1**. The **geotype** column stores the name of the subclass stored in the **g1** ST_Geometry column:

```
CREATE TABLE dimension_test (geotype varchar(20),
                             g1      ST_Geometry);
```

The following INSERT statements insert a sample subclass into the **dimension_test** table:

```
INSERT INTO dimension_test VALUES(
    'Point',
    ST_PointFromText('point (10.02 20.01)',1000)
);

INSERT INTO dimension_test VALUES(
    'Linestring',
    ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO dimension_test VALUES(
    'Polygon',
    ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02 34.15,
19.15 33.94,10.02 20.01))',1000)
);

INSERT INTO dimension_test VALUES(
    'Multipoint',
    ST_MPointFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO dimension_test VALUES(
    'Multilinestring',
    ST_MLineFromText('multilinestring ((10.02 20.01,10.32
23.98,11.92 25.64),(9.55 23.75,15.36 30.11))',1000)
);

INSERT INTO dimension_test VALUES(
    'Multipolygon',
```

```

    ST_MPolyFromText('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52
32.87,52.43 31.90,51.71 21.73)))',1000)
);

```

The SELECT statement lists the subclass name stored in the **geotype** column with the dimension of that geotype:

```

SELECT geotype, ST_Dimension(g1) Dimension
FROM dimension_test;

```

geotype	dimension
Point	0
Linestring	1
Polygon	2
Multipoint	0
Multilinestring	1
Multipolygon	2

The ST_Disjoint() function

The **ST_Disjoint()** function takes two geometries and returns t (TRUE) if the two geometries are completely non-intersecting; otherwise, it returns f (FALSE).

Syntax

```

ST_Disjoint(g1 ST_Geometry, g2 ST_Geometry)

```

Return type

BOOLEAN

Example

An insurance company wants to assess the insurance coverage for the town's hospital, nursing homes, and schools. Part of this process includes determining the threat the hazardous waste sites pose to each institution. At this time, the insurance company wants to consider only those institutions that are not at risk of contamination. The GIS consultant hired by the insurance company has been commissioned to locate all institutions that are outside a five-mile radius of a hazardous waste storage facility.

The **sensitive_areas** table contains several columns that describe the threatened institutions in addition to the **zone** column, which stores the institutions' polygon geometries:

```

CREATE TABLE sensitive_areas (id      integer,
                              name    varchar(128),
                              size    float,
                              type    varchar(10),
                              zone    ST_Polygon);

```

The **hazardous_sites** table stores the identity of the sites in the **site_id** and **name** columns, while the actual geographic location of each site is stored in the **location** point column:

```

CREATE TABLE hazardous_sites (site_id integer,
                              name     varchar(40),
                              location ST_Point);

```

The `SELECT` statement lists the names of all sensitive areas that are outside the five-mile radius of a hazardous waste site:

```
SELECT sa.name
FROM sensitive_areas sa, hazardous_sites hs
WHERE ST_Disjoint(ST_Buffer(hs.location,(5 * 5280)), sa.zone);
```

You could also use the `ST_Intersects()` function to perform this query, because `ST_Intersects()` and `ST_Disjoint()` return the opposite results:

```
SELECT sa.name
FROM sensitive_areas sa, hazardous_sites hs
WHERE NOT ST_Intersects(ST_Buffer(hs.location,(5 * 5280)), sa.zone);
```

The following figure shows that the nursing home is the only sensitive area for which the `ST_Disjoint()` function will return `t` (TRUE) when comparing sensitive sites to the five-mile radius of the hazardous waste sites. The `ST_Disjoint()` function returns `t` whenever two geometries do not intersect in any way.

Figure 8-5. Sensitive Sites and Hazardous Waste Sites

Related reference:

- “The `ST_Disjoint()` function” on page 7-2
- “The `ST_Disjoint()` function” on page 7-17

The `SE_Dissolve()` function

The `SE_Dissolve()` function is an aggregate function that computes the union of geometries of the same dimension (if there is just one geometry that satisfies your query, it is returned unaltered).

Syntax

```
SE_Dissolve (g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The following example creates a single multipolygon from the individual hexagons inserted into the **honeycomb** table:

```
CREATE TABLE honeycomb (cell_id int, hex_cell ST_Polygon);

INSERT INTO honeycomb
  VALUES (1, '0 polygon((5 10,7 7,10 7,12 10,10 13,7 13,5 10))');
INSERT INTO honeycomb
  VALUES (2, '0 polygon((12 4,15 4,17 7,15 10,12 10,10 7,12 4))');
INSERT INTO honeycomb
  VALUES (3, '0 polygon((17 7,20 7,22 10,20 13,17 13,15 10,17 7))');
INSERT INTO honeycomb
  VALUES (4, '0 polygon((15 10,17 13,15 16,12 16,10 13,12 10,15 10))');
```

```
SELECT SE_Dissolve(hex_cell) FROM honeycomb;
```

```
se_dissolve 0 MULTIPOLYGON (((5 10, 7 7, 10 7, 12 4, 15 4, 17 7, 20 7, 22
10, 20 13, 17 13, 15 16, 12 16, 10 13, 7 13, 5 10)))
```

Related reference:

“The SE_Dissolve() function” on page 7-11

The ST_Distance() function

The **ST_Distance()** function returns the shortest distance separating two geometries.

Syntax

```
ST_Distance(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

DOUBLE PRECISION

Example

The city engineer needs a list of all buildings within one foot of any lot line.

The **building_id** column of the **buildingfootprints** table uniquely identifies each building. The **lot_id** column identifies the lot each building belongs to. The **footprints** multipolygon stores the geometry of each building's footprint:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id       integer,
                                footprint    ST_MultiPolygon);
```

The **lots** table stores the **lot_id** that uniquely identifies each lot and the **lot** ST_MultiPolygon that contains the lot geometry:

```
CREATE TABLE lots (lot_id integer,
                   lot     ST_MultiPolygon);
```

The following query returns a list of building IDs that are within one foot of their lot lines. The **ST_Distance()** function performs a spatial join on the **footprints** and **lot** ST_MultiPolygon columns. However, the equijoin between **bf.lot_id** and **lots.lot_id** ensures that only the ST_MultiPolygons belonging to the same lot are compared by the **ST_Distance()** function:

```

SELECT bf.building_id
FROM buildingfootprints bf, lots
WHERE bf.lot_id = lots.lot_id
AND ST_Distance(footprint,Tot) <= 1.0;

```

The ST_DistanceToPoint() function

The **ST_DistanceToPoint()** function returns the distance from the start of the line to the specified point. Z coordinates and measures are ignored.

Syntax

```

ST_DistanceToPoint (ST_LineString, ST_Point)
ST_DistanceToPoint (ST_MultiLineString, ST_Point)

```

Return type

DOUBLE

Example

The following SQL statement creates the **sample_geometries** table with two columns. The ID column uniquely identifies each row. The **geometry** ST_LineString column stores sample geometries.

```

CREATE TABLE sample_geometries(id INTEGER, geometry ST_LINESTRING);

```

The following SQL statement inserts two rows into the **sample_geometries** table:

```

INSERT INTO sample_geometries(id, geometry)
VALUES
(1,ST_LineString('LINESTRING ZM(0 0 0 0, 10 100 1000 10000)',1)),
(2,ST_LineString('LINESTRING ZM(10 100 1000 10000, 0 0 0 0)',1));

```

The following SELECT statement and the corresponding result set show how to use the **ST_DistanceToPoint()** function to find the distance to the point at the location (1.5, 15.0):

```

SELECT ID, DECIMAL(ST_DistanceToPoint(geometry,ST_Point(1.5,15.0,1)),10,5)
AS DISTANCE FROM sample_geometries;

```

ID	DISTANCE
1	15.07481
2	85.42394

2 record(s) selected.

The ST_EndPoint() function

The **ST_EndPoint()** function returns the last point of a linestring.

Syntax

```

ST_EndPoint(1n1 ST_LineString)

```

Return type

ST_Point

Example

The **endpoint_test** table stores the **gid** INTEGER column, which uniquely identifies each row and the **ln1** ST_LineString column that stores linestrings:

```
CREATE TABLE endpoint_test (gid integer,
                             ln1 ST_LineString);
```

The following INSERT statements insert linestrings into the **endpoint_test** table. The first linestring does not have Z coordinates or measures, while the second one does:

```
INSERT INTO endpoint_test VALUES(
    1,
    ST_LineFromText('linestring (10.02 20.01,23.73 21.92,30.10 40.23)',1000)
);
```

```
INSERT INTO endpoint_test VALUES(
    2,
    ST_LineFromText('linestring zm (10.02 20.01 5.0 7.0,23.73 21.92
6.5 7.1,30.10 40.23 6.9 7.2)',1000)
);
```

The following query lists the **gid** column with the output of the **ST_EndPoint()** function. The **ST_EndPoint()** function generates an ST_Point geometry:

```
SELECT gid, ST_EndPoint(ln1) Endpoint
FROM endpoint_test;
```

```
gid      1
endpoint 1000 POINT (30.1 40.23)
```

```
gid      2
endpoint 1000 POINT ZM (30.1 40.23 6.9 7.2)
```

See also

“The ST_StartPoint() function” on page 8-105

The ST_Envelope() function

The **ST_Envelope()** function returns the bounding box of a geometry object.

This is usually a rectangle, but the envelope of a point is the point itself, and the envelope of a horizontal or vertical linestring is a linestring represented by the endpoints of the source geometry.

Syntax

```
ST_Envelope(g1 ST_Geometry)
```

Return type

ST_Geometry

Example

The **geotype** column of the **envelope_test** table stores the name of the geometry subclass stored in the **g1** ST_Geometry column:

```
CREATE TABLE envelope_test (geotype varchar(20),
                             g1      ST_Geometry);
```

The following INSERT statements insert each geometry subclass into the **envelope_test** table:

```

INSERT INTO envelope_test VALUES(
    'Point',
    ST_PointFromText('point (10.02 20.01)',1000)
);

INSERT INTO envelope_test VALUES(
    'Linestring',
    ST_LineFromText('linestring (10.01 20.01, 10.01 30.01, 10.01 40.01)', 1000)
);

INSERT INTO envelope_test VALUES(
    'Linestring',
    ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)', 1000)
);

INSERT INTO envelope_test VALUES(
    'Polygon',
    ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94, 10.02 20.01))',1000)
);

INSERT INTO envelope_test VALUES(
    'Multipoint',
    ST_MPointFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)', 1000)
);

INSERT INTO envelope_test VALUES(
    'Multilinestring',
    ST_MLineFromText('multilinestring ((10.01 20.01,20.01
20.01,30.01 20.01), (30.01 20.01,40.01 20.01,50.01 20.01))',1000)
);

INSERT INTO envelope_test VALUES(
    'Multilinestring',
    ST_MLineFromText('multilinestring ((10.02 20.01,10.32
23.98,11.92 25.64),(9.55 23.75,15.36 30.11))',1000)
);

INSERT INTO envelope_test VALUES(
    'Multipolygon',
    ST_MPolyFromText('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52
32.87,52.43 31.90,51.71 21.73)))',1000)
);

```

The following query lists the subclass name and its envelope. The **ST_Envelope()** function returns a point, a linestring, or a polygon:

```

SELECT geotype, ST_Envelope(g1) Envelope
FROM envelope_test;

```

```

geotype    Point

“The SE_BoundingBox() function” on page 8-18

The ST_EnvelopeAsGML() function

The **ST_EnvelopeAsGML()** function takes a geometry value returned by ST_Envelope and generates a GML3 Envelope element.

Syntax

ST_EnvelopeAsGML(p ST_Geometry)

Return type

ST_Geometry

Example

```
ST_EnvelopeFromGML(ST_Envelope(ST_LineFromText('LINESTRING(1 2, 3 4)', 1003)))
```

Output:

```
<gml:Envelope srsName="EPSG:1234">  
  <gml:lowerCorner> 1 2</gml:lowerCorner>  
  <gml:upperCorner> 3 4 </gml:upperCorner>  
</gml:Envelope>
```

The SE_EnvelopeAsKML() function

The **SE_EnvelopeAsKML()** function takes a geometry value returned by ST_Envelope and returns it as a KML LatLonBox.

Syntax

SE_EnvelopeAsKML(p ST_Geometry)

Return type

ST_Geometry

Example

```
EXECUTE FUNCTION SE_EnvelopeAsKML(ST_PolyFromText('POLYGON  
  ((-124.21160602 25.8373769872,  
  -67.1589579416 25.8373769872,  
  -67.1589579416 49.384359066,  
  -124.21160602 49.384359066,  
  -124.21160602 25.8373769872))',3));
```

Output:

```

<LatLonBox>
  <north>49.384359066</north>
  <south>25.8373769872</south>
  <east>-67.1589579416</east>
  <west>-124.21160602</west>
</LatLonBox>

```

The ST_EnvelopeFromGML() function

The **ST_EnvelopeFromGML()** function takes a GML2 or GML3 string representation of an envelope and an optional spatial reference ID and returns a geometry object.

If the **srsName** attribute is specified in the GML string, then a corresponding entry in the **spatial_references** table must exist unless it is specified as UNKNOWN or DEFAULT.

Syntax

```

ST_EnvelopeFromGML(gml_string lvarchar)
ST_EnvelopeFromGML(gml_string lvarchar, SRID integer)

```

Return type

A four sided ST_Polygon representing the envelope.

Example

```

ST_EnvelopeFromGML('<gml:Envelope>
  <gml:lowerCorner> -180.0 -90.0</gml:lowerCorner>
  <gml:upperCorner> 180.0 90.0 </gml:upperCorner>
</gml:Envelope>', 1003)

```

The SE_EnvelopeFromKML() function

The **SE_EnvelopeFromKML()** function takes a KML LatLonBox or LatLonAltBox and an optional spatial reference ID and returns a polygon.

The LatLonBox and LatLonAltBox contain four coordinates: north, south, east, and west, that are used to form the traditional pair of SW, NE coordinates usually found with bounding boxes. LatLonAltBox also contains the elements minAltitude and maxAltitude, and while those will be accepted as valid tags in the KML fragment, they are not used to form a Z-polygon. Only 2-D polygons are returned.

Syntax

```

SE_EnvelopeFromKML(kml_string lvarchar)
SE_EnvelopeFromKML(kml_string lvarchar, SRID integer)

```

Return type

A four sided ST_Polygon representing the envelope.

Example

In this example, the KML LatLonBox includes four coordinates:

```

EXECUTE FUNCTION SE_EnvelopeFromKML('<LatLonBox><north>34.54356</north>
  <south>33.543634</south>
  <east>-83.21454</east>
  <west>-86.432536</west>',4);

```

Output:

```
4 POLYGON ((-86.3253600195 33.5436340112, -83.2145400212 33.543630112,
-83.2145400212 34.5435600828, -86.3253600195 34.5435600828,
-86.3253600195 33.5436340112))
```

In this example, the KML LatLonAltBox includes the four coordinates as well as the minAltitude, maxAltitude, and altitudeMode attributes:

```
EXECUTE FUNCTION SE_EnvelopeFromKML('<LatLonAltBox><north>45.0</north>
<south>42.0</south><east>-80.0</east><west>-82.0</west>
<minAltitude>0</minAltitude><maxAltitude>0</maxAltitude>
<altitudeMode>clampToGround</altitudeMode>',4);
```

However, the output only includes the four coordinates:

```
4 POLYGON((-82.0 42.0, -80.0 42.0, -80.0 45.0, -82.0 45.0, -82.0 42.0))
```

The SE_EnvelopesIntersect() function

The **SE_EnvelopesIntersect()** function returns t (TRUE) if the envelopes of two geometries intersect; otherwise, it returns f (FALSE).

Syntax

```
SE_EnvelopesIntersect(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The **get_window()** function retrieves the display window coordinates from the application. The window parameter is actually a polygon shape structure containing a string of coordinates that represents the display polygon. The **SE_PolygonFromShape()** function converts the display window shape into a polygon that the **SE_EnvelopesIntersect()** function uses as its intersection envelope. All **sensitive_areas zone** polygons that intersect the interior or boundary of the display window are returned. Each polygon is fetched from the result set and passed to the **draw_polygon()** function:

```
/* Get the display window coordinates as a polygon shape. */
get_window(&query_shape_buf, &query_shape_len);

/* Create the SQL expression. The envelopesintersect function limits
 * the result set to only those zone polygons that intersect the
 * envelope of the display window. */
sprintf(sql_stmt,
        "select SE_AsShape(zone) ",
        "from sensitive_areas where ",
        "SE_EnvelopesIntersect(zone,SE_PolyFromShape(?,1))");

/* Prepare the SQL statement. */
SQLPrepare(hstmt, (UCHAR *)sql_stmt, SQL_NTS);

/* Bind the query geometry parameter. */
pcbvalue1 = query_shape_len;
SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_BINARY,
                  SQL_INFX_UDT_LVARCHAR, query_shape_len, 0,
                  query_shape_buf, query_shape_len, &pcbvalue1);

/* Execute the query. */
rc = SQLExecute(hstmt);
```

```

/* Assign the results of the query (the Zone polygons) to the
   fetched_shape_buf variable. */
SQLBindCol(hstmt, 1, SQL_C_BINARY, fetched_shape_buf, 100000,
           &fetched_shape_len);

/* Fetch each polygon within the display window and display it. */
while (SQL_SUCCESS == (rc = SQLFetch(hstmt)))
    draw_polygon(fetched_shape_buf);

```

The ST_Equals() function

The **ST_Equals()** function compares two geometries and returns t (TRUE) if the geometries are spatially equal; otherwise, it returns f (FALSE).

Using the **ST_Equals()** function is functionally equivalent to using **ST_IsEmpty(ST_SymDifference(a,b))**.

The **ST_Equals()** function is computationally intensive and you should consider whether you could use the **Equals()** function instead, which does a byte-by-byte comparison of two objects. The **Equals()** function is a system function; it is called in SQL statements when you use the = operator, as shown in the second SELECT statement in the following example.

To illustrate the difference between **ST_Equals()** and **Equals()**, consider the following example:

```

CREATE TABLE equal_test (id integer,
                        line ST_LineString);

INSERT INTO equal_test VALUES
  (1, ST_LineFromText('linestring(10 10, 20 20)', 1000));

INSERT INTO equal_test VALUES
  (2, ST_LineFromText('linestring(20 20, 10 10)', 1000));

```

The following query returns both rows, because **ST_Equals()** determines that both linestrings are spatially equivalent:

```

SELECT id FROM equal_test
  WHERE ST_Equals (line, ST_LineFromText('linestring(10 10, 20 20)', 1000));

   id
   --
    1
    2

```

The following query only returns the first row, because **Equals()** only performs a memory comparison of the linestrings:

```

SELECT id FROM equal_test
  WHERE line = ST_LineFromText('linestring(10 10, 20 20)', 1000);

   id
   --
    1

```

Syntax

```
ST_Equals(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The city GIS technician suspects that some of the data in the **buildingfootprints** table was somehow duplicated. To alleviate concern, the technician queries the table to determine if any of the footprints multipolygons are equal.

The **buildingfootprints** table is created with the following statement. The **building_id** column uniquely identifies the buildings, the **lot_id** identifies the building's lot, and the **footprint** multipolygon stores the building's geometry:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);
```

The **buildingfootprints** table is spatially joined to itself by the **ST_Equals()** function, which returns 1 whenever it finds two multipolygons that are equal. The **bf1.building_id <> bf2.building_id** condition eliminates the comparison of a geometry to itself:

```
SELECT bf1.building_id, bf2.building_id
FROM buildingfootprints bf1, buildingfootprints bf2
WHERE ST_Equals(bf1.footprint,bf2.footprint)
AND bf1.building_id <> bf2.building_id;
```

Related reference:

"The **ST_Equals()** function" on page 7-1

"The **ST_Equals()** function" on page 7-17

The **ST_ExteriorRing()** function

The **ST_ExteriorRing()** function returns the exterior ring of a polygon as a linestring.

Syntax

```
ST_ExteriorRing(p11 ST_Polygon)
```

Return type

ST_LineString

Example

An ornithologist studying the bird population on several South Sea islands knows that the feeding zone of the bird species of interest is restricted to the shoreline. As part of the calculation of the island's carrying capacity, the ornithologist requires the islands' perimeters. Some of the islands are so large, they have several ponds on them. However, the shorelines of the ponds are inhabited exclusively by another more aggressive bird species. Therefore, the ornithologist requires the perimeter of the exterior ring only of the islands.

The **ID** and **name** columns of the **islands** table identifies each island, while the **land** polygon column stores the island's geometry:

```
CREATE TABLE islands (id integer,
                       name varchar(32),
                       land ST_Polygon);
```

The **ST_ExteriorRing()** function extracts the exterior ring of each island polygon as a linestring. The length of the linestring is calculated by the **ST_Length()** function. The linestring lengths are summarized by the **SUM** operator:

```
SELECT SUM(ST_Length(ST_ExteriorRing(land)))
FROM islands;
```

As shown in the following figure, the exterior rings of the islands represent the ecological interface each island shares with the sea. Some of the islands have lakes, which are represented by the interior rings of the polygons.

Figure 8-6. Islands and lakes

The SE_Generalize() function

The **SE_Generalize()** function reduces the number of vertices in an `ST_LineString`, `ST_MultiLineString`, `ST_Polygon`, or `ST_MultiPolygon` while preserving the general character of the geometric shape.

This function uses the Douglas-Peucker line-simplification algorithm. The vertex sequence of the input geometry is recursively subdivided until a run of vertices can be replaced by a straight-line segment, with no vertex in that run deviating from the straight line by more than the threshold.

Z values, if present, are not considered when simplifying a set of vertices.

Syntax

```
SE_Generalize (g1 ST_Geometry, threshold float)
```

Return type

`ST_Geometry`, unless the input geometry is an `ST_Point`, `ST_MultiPoint`, or an empty geometry of any subtype, in which case this function returns `NULL`

Example

```
CREATE TABLE jagged_lines(line ST_LineString);

INSERT INTO jagged_lines VALUES(
  "0 linestring(10 10, 20 20, 20 18, 30 30, 30 28, 40 40)"
);

-- Small threshold; no vertices removed:
SELECT SE_Generalize(line, 0.5) FROM jagged_lines;

(expression) 0 LINESTRING (10 10, 20 20, 20 18, 30 30, 30 28, 40 40)

-- Larger threshold; some vertices removed:
SELECT SE_Generalize(line, 2) FROM jagged_lines;

(expression) 0 LINESTRING (10 10, 40 40)
```

Related reference:

“The SE_Generalize() function” on page 7-15

The ST_GeometryN() function

The **ST_GeometryN()** function takes a takes an ST_GeomCollection (ST_MultiPoint, ST_MultiLineString, or ST_MultiPolygon) and an INTEGER index and returns the *n*th **ST_Geometry** object in the collection.

Syntax

```
ST_GeometryN(mpt1 ST_MultiPoint, index integer)
ST_GeometryN(mln1 ST_MultiLineString, index integer)
ST_GeometryN(mp11 ST_MultiPolygon, index integer)
```

Return type

ST_Geometry

Example

The city engineer wants to know which building footprints are all inside the first polygon of the **lots** ST_MultiPolygon.

The **building_id** column uniquely identifies each row of the **buildingfootprints** table. The **lot_id** column identifies the building's lot. The **footprint** column stores the building geometries:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);

CREATE TABLE lots (lot_id integer,
                   lot ST_MultiPolygon);
```

The query lists the **buildingfootprints** table values of **building_id** and **lot_id** for all building footprints that are all within the first lot polygon. The **ST_GeometryN()** function returns a first lot polygon element in the ST_MultiPolygon:

```
SELECT bf.building_id,bf.lot_id
FROM buildingfootprints bf,lots
WHERE ST_Within(footprint,ST_GeometryN(lot,1))
AND bf.lot_id = lots.lot_id;
```

The ST_GeometryType() function

The **ST_GeometryType()** function takes an ST_Geometry object and returns its geometry type as a string.

Syntax

```
ST_GeometryType (g1 ST_Geometry)
```

Return type

VARCHAR(32) containing one of the following text strings:

- st_point
- st_linestring
- st_polygon

- st_multipoint
- st_multilinestring
- st_multipolygon

Example

The **geometrytype_test** table contains the **g1** ST_Geometry column:

```
CREATE TABLE geometrytype_test(g1 ST_Geometry);
```

The following INSERT statements insert each geometry subclass into the **g1** column:

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('point (10.02 20.01)',1000)
);
```

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('linestring (10.01 20.01, 10.01 30.01, 10.01 40.01)', 1000)
);
```

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('polygon ((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94, 10.02 20.01))',1000)
);
```

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)', 1000)
);
```

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('multilinestring ((10.02 20.01,10.32
23.98,11.92 25.64),(9.55 23.75,15.36 30.11))',1000)
);
```

```
INSERT INTO geometrytype_test VALUES(
  ST_GeomFromText('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94 ,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52
32.87,52.43 31.90,51.71 21.73)))'
,1000)
);
```

The following query lists the geometry type of each subclass stored in the **g1** geometry column:

```
SELECT ST_GeometryType(g1) Geometry_type
FROM geometrytype_test;
```

```
geometry_type st_point
```

```
geometry_type st_linestring
```

```
geometry_type st_polygon
```

```
geometry_type st_multipoint
```

```
geometry_type st_multilinestring
```

```
geometry_type st_multipolygon
```

The ST_GeomFromGML() function

The **ST_GeomFromGML()** function takes a GML2 or GML version 3 string representation and an optional spatial reference ID and returns a geometry object.

If the **srsName** attribute is specified in the GML string, a corresponding entry must exist in the **spatial_references** table, or it must be specified as UNKNOWN or DEFAULT. The GML representation can include Z and M measures, but must include the appropriate **srsDimension** attribute. The following table describes the corresponding geometry values for each **srsDimension** value.

Table 8-5. Geometry values for srsDimension values

srsDimension value	Geometry value
2	A geometry value with only X and Y coordinate values.
3	A geometry value with X, Y, and Z coordinate values in GML version 3 or using the <coordinates> tag in GML 2. A geometry value with X, Y and measure values if the <X>, <Y>, and <M> tags are used in the <coord> elements of the GML representation.
4	A geometry value with X, Y, Z, and measure coordinate values.

Syntax

```
ST_GeomFromGML(gml_string lvarchar)
ST_GeomFromGML(gml_string lvarchar, SRID integer)
```

For SRID, specify 2 if the GML conforms to GML version 2, or specify 3 for GML3. The default is 3.

Return type

ST_Geometry

Example

The **geometry_test** table contains the INTEGER **gid** column, which uniquely identifies each row, and the **g1** column, which stores the geometry:

```
CREATE TABLE geometry_test (gid smallint, g1 ST_Geometry);
```

The following INSERT statements insert the data into the **gid** and **g1** columns of the **geometry_test** table. The **ST_GeomFromGML()** function converts the GML text representation of each geometry into its corresponding instantiable subclass:

```
INSERT INTO geometry_test VALUES (
1,
ST_GeomFromGML('<gml:Point srsName="DEFAULT" srsDimension="2">
  <gml:pos>10.02 20.01</gml:pos></gml:Point>',1000)) ;

INSERT INTO geometry_test VALUES (
2,
ST_GeomFromGML('<gml:LineString srsName="DEFAULT" srsDimension="2">
  <gml:posList dimension="2">10.01 20.01 10.01 30.01 10.01 40.01
</gml:posList>
</gml:LineString>',1000)) ;

INSERT INTO geometry_test VALUES (
3,
ST_GeomFromGML('<gml:Polygon srsName="DEFAULT" srsDimension="2">
  <gml:exterior>
  <gml:LinearRing>
  <gml:posList dimension="2">
    10.02 20.01 19.15 33.94 25.02 34.15 11.92 35.64 10.02 20.01
  </gml:posList>
  </gml:LinearRing>
```

```

        </gml:exterior>
        </gml:Polygon>',1000)) ;

INSERT INTO geometry_test VALUES (
4,
ST_GeomFromGML('<gml:MultiPoint srsName="DEFAULT" srsDimension="2">
  <gml:PointMember>
    <gml:Point srsName="DEFAULT" srsDimension="2">
      <gml:pos>10.02 20.01</gml:pos>
    </gml:Point>
  </gml:PointMember><gml:PointMember>
    <gml:Point srsName="DEFAULT" srsDimension="2">
      <gml:pos>10.32 23.98</gml:pos>
    </gml:Point>
  </gml:PointMember>
  <gml:PointMember>
    <gml:Point srsName="DEFAULT" srsDimension="2">
      <gml:pos>11.92 25.64</gml:pos>
    </gml:Point>
  </gml:PointMember>
</gml:MultiPoint>',1000)) ;

INSERT INTO geometry_test VALUES (
5,
ST_GeomFromGML('<gml:MultiLineString srsName="DEFAULT" srsDimension="2">
  <gml:LineStringMember>
    <gml:LineString srsName="DEFAULT" srsDimension="2">
      <gml:posList dimension="2">10.02 20.01 10.32 23.98 11.92 25.64
    </gml:posList>
    </gml:LineString>
  </gml:LineStringMember>
  <gml:LineStringMember>
    <gml:LineString srsName="DEFAULT" srsDimension="2">
      <gml:posList dimension="2">9.55 23.75 15.36 30.11</gml:posList>
    </gml:LineString>
  </gml:LineStringMember>
</gml:MultiLineString>',1000)) ;

INSERT INTO geometry_test VALUES (
6,
ST_GeomFromGML('<gml:MultiPolygon srsName="DEFAULT" srsDimension="2">
  <gml:PolygonMember><gml:Polygon srsName="DEFAULT" srsDimension="2">
    <gml:exterior>
      <gml:LinearRing>
        <gml:posList dimension="2">
          10.02 20.01 19.15 33.94 25.02 34.15 11.92 35.64 10.02 20.01
        </gml:posList>
      </gml:LinearRing>
    </gml:exterior>
  </gml:Polygon>
</gml:PolygonMember>
  <gml:PolygonMember>
    <gml:Polygon srsName="DEFAULT" srsDimension="2">
      <gml:exterior><gml:LinearRing>
        <gml:posList dimension="2">
          51.71 21.73 73.36 27.04 71.52 32.87 52.43 31.9 51.71 21.73
        </gml:posList>
      </gml:LinearRing>
    </gml:exterior>
  </gml:Polygon>
</gml:PolygonMember>
</gml:MultiPolygon>',1000)) ;

```

The ST_GeomFromKML() function

The `ST_GeomFromKML()` function takes a KML fragment and returns an `ST_Geometry` corresponding to the fragment.

Syntax

```
ST_GeomFromKML(kml_string lvarchar)
```

Return type

Depends on the KML fragment type, as shown in the following table.

Table 8-6. KML fragment to return type mapping

KML fragment	Return type
Point	ST_Point
LineString	ST_LineString
Polygon	ST_Polygon
MultiGeometry plus Point	ST_MultiPoint
MultiGeometry plus LineString	ST_MultiLineString
MultiGeometry plus Polygon	ST_MultiPolygon

Example

The `geometry_test` table contains the `INTEGER` `gid` column, which uniquely identifies each row, and the `geom` column, which stores the geometry:

```
CREATE TABLE geometry_test (gid INTEGER, geom ST_Geometry);
```

The following `INSERT` statements insert the data into the `gid` and `geom` columns of the `geometry_test` table. The `ST_GeomFromKML()` function converts the KML text representation of each geometry into its corresponding instantiable subclass:

```
INSERT INTO geometry_test VALUES(1,ST_GeomFromKML('<Point><coordinates>
10.02,20.01</coordinates></Point>',4))
```

```
INSERT INTO geometry_test VALUES(2,ST_GeomFromKML('<LineString><coordinates>
10.01,20.01 20.01,30.01 30.01,40.01
</coordinates></LineString>',4));
```

The SE_GeomFromShape() function

The `SE_GeomFromShape()` function takes a shape and a spatial reference ID and returns a geometry object.

Syntax

```
SE_GeomFromShape(s1 lvarchar, SRID integer)
```

Return type

`ST_Geometry`

Example

The following C code fragment contains ODBC functions included with the spatial data type functions that insert data into the `lots` table.

The **lots** table was created with two columns: the **lot_id**, which uniquely identifies each lot, and the **lot** polygon column, which contains the geometry of each lot:

```
CREATE TABLE lots (lot_id integer,
                   lot      ST_MultiPolygon);
```

The **SE_GeomFromShape()** function converts shapes into an IBM Informix spatial geometry. The entire INSERT statement is copied into **shp_sql**. The INSERT statement contains parameter markers to accept the **lot_id** and **lot** data, dynamically:

```
/* Create the SQL insert statement to populate the lots
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO lots (lot_id, lot) "
        "VALUES(?, SE_GeomFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry to the second parameter. */
pcbvalue2 = lot_shape_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_shape_len, 0,
                      lot_shape_buf, lot_shape_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The **ST_GeomFromText()** function

The **ST_GeomFromText()** function takes a well-known text representation and a spatial reference ID and returns a geometry object.

Syntax

```
ST_GeomFromText(wkt lvarchar, SRID integer)
```

Return type

ST_Geometry

Example

The **geometry_test** table contains the **INTEGER gid** column, which uniquely identifies each row, and the **g1** column, which stores the geometry:

```
CREATE TABLE geometry_test (gid smallint,
                             g1 ST_Geometry);
```

The following INSERT statements insert the data into the **gid** and **g1** columns of the **geometry_test** table. The **ST_GeomFromText()** function converts the text representation of each geometry into its corresponding instantiable subclass:

```
INSERT INTO geometry_test VALUES(
    1,
    ST_GeomFromText('point (10.02 20.01)',1000)
);
```

```

INSERT INTO geometry_test VALUES(
    2,
    ST_GeomFromText('linestring (10.01 20.01, 10.01 30.01, 10.01 40.01)',1000)
);

INSERT INTO geometry_test VALUES(
    3,
    ST_GeomFromText('polygon ((10.02 20.01, 11.92 35.64, 25.02
34.15, 19.15 33.94, 10.02 20.01))',1000)
);

INSERT INTO geometry_test VALUES(
    4,
    ST_GeomFromText('multipoint (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO geometry_test VALUES(
    5,
    ST_GeomFromText('multilinestring ((10.02 20.01, 10.32 23.98,
11.92 25.64),(9.55 23.75,15.36 30.11))',1000)
);

INSERT INTO geometry_test VALUES(
    6,
    ST_GeomFromText('multipolygon (((10.02 20.01, 11.92 35.64,
25.02 34.15, 19.15 33.94, 10.02 20.01)),((51.71 21.73, 73.36
27.04, 71.52 32.87, 52.43 31.90, 51.71 21.73)))',1000)
);

```

The ST_GeomFromWKB() function

The **ST_GeomFromWKB()** function takes a well-known binary representation and a spatial reference ID to return a geometry object.

Syntax

```
ST_GeomFromWKB(WKB lvarchar, SRID integer)
```

Return type

ST_Geometry

Example

The following C code fragment contains ODBC functions included with the IBM Informix spatial data type functions that insert data into the **lots** table.

The **lots** table was created with two columns: the **lot_id**, which uniquely identifies each lot, and the **lot** polygon column, which contains the geometry of each lot:

```
CREATE TABLE lots (lot_id integer,
                   lot      ST_MultiPolygon);
```

The **ST_GeomFromWKB()** function converts WKB representations into Informix spatial geometry. The entire INSERT statement is copied into a **wkb_sql** CHAR string. The INSERT statement contains parameter markers to accept the **lot_id** and **lot** data, dynamically:

```

/* Create the SQL insert statement to populate the lots
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO lots (lot_id, lot) "
```

```

VALUES(?, ST_GeomFromWKB(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry to the second parameter. */
pcbvalue2 = lot_wkb_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_wkb_len, 0,
                      lot_wkb_buf, lot_wkb_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The SE_InRowSize() function

The **SE_InRowSize()** function returns the size of the in-row portion of a geometry. Geometries which are less than 930 bytes are stored entirely in-row: that is, the entire value is stored in a table's dbspace.

The **SE_InRowSize()** function returns the size of the in-row portion of a geometry. Geometries which are less than 930 bytes are stored entirely in-row: that is, the entire value is stored in a table's dbspace.

You can use this function to obtain an estimate of the amount of disk space consumed by one or more geometries. However, this function does not account for dbspace and sbospace overhead, so cannot be used to obtain an exact total.

Syntax

```
SE_InRowSize(ST_Geometry)
```

Return type

INTEGER

See also

"The SE_OutOfRowSize() function" on page 8-87

"The SE_TotalSize() function" on page 8-107

The ST_InteriorRingN() function

The **ST_InteriorRingN()** function returns the *n*th interior ring of a polygon as an ST_LineString.

The order of the rings cannot be predefined since the rings are organized according to the rules defined by the internal geometry verification routines and not by geometric orientation.

Syntax

```
ST_InteriorRingN(p11 ST_Polygon, index integer)
```

Return type

ST_LineString

Example

An ornithologist studying the bird population on several South Sea islands knows that the feeding zone of this passive species is restricted to the seashore. Some of the islands are so large they have several lakes on them. The shorelines of the lakes are inhabited exclusively by another more aggressive species. The ornithologist knows that if the perimeter of the ponds on each island exceeds a certain threshold, the aggressive species will become so numerous that it will threaten the passive seashore species. Therefore, the ornithologist requires the aggregated perimeter of the interior rings of the islands.

The following figure shows the exterior rings of the islands that represent the ecological interface each island shares with the sea. Some of the islands have lakes, which are represented by the interior rings of the polygons.

Figure 8-7. Islands and lakes.

The **ID** and **name** columns of the **islands** table identifies each island, while the **land** ST_Polygon column stores the island geometry:

```
CREATE TABLE islands (id    integer,
                       name  varchar(32),
                       land  ST_Polygon);
```

This ODBC code fragment uses the **ST_InteriorRingN()** function to extract the interior ring (lake) from each island polygon as a linestring. The perimeter of the linestring returned by the **ST_Length()** function is totaled and displayed along with the island ID:

```
/* Prepare and execute the query to get the island IDs and number
   of lakes (interior rings); */
sprintf(sql_stmt,
        "SELECT id, ST_NumInteriorRing(land) FROM islands");

/* Allocate memory for the island cursor */
rc = SQLAllocHandle (SQL_HANDLE_STMT, hdbc, &island_cursor);

rc = SQLExecDirect (island_cursor, (UCHAR *)sql_stmt, SQL_NTS);

/* Bind the island table's id column to island_id. */
rc = SQLBindCol (island_cursor, 1, SQL_C_SLONG,
                &island_id, 0, &id_ind);

/* Bind the result of ST_NumInteriorRing(land) to num_lakes. */
rc = SQLBindCol (island_cursor, 2, SQL_C_SLONG,
                &num_lakes, 0, &lake_ind);
```

```

/* Allocate memory to the SQL statement handle lake_cursor. */
rc = SQLAllocHandle (SQL_HANDLE_STMT, hdbc, &lake_cursor);

/* Prepare the query to get the length of an interior ring. For
 * efficiency, we only prepare this query once. */
sprintf (sql_stmt,
        "SELECT ST_Length(ST_InteriorRingN(land, ?))"
        "FROM islands WHERE id = ?");
rc = SQLPrepare (lake_cursor, (UCHAR *)sql_stmt, SQL_NTS);

/* Bind the lake_number to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (lake_cursor, 1, SQL_PARAM_INPUT, SQL_C_LONG,
        SQL_INTEGER, 0, 0,
        &lake_number, 0, &pcbvalue1);

/* Bind the island_id to the second parameter. */
pcbvalue2 = 0;
rc = SQLBindParameter (lake_cursor, 2, SQL_PARAM_INPUT, SQL_C_LONG,
        SQL_INTEGER, 0, 0,
        &island_id, 0, &pcbvalue2);

/* Bind the result of the ST_Length function to lake_perimeter. */
rc = SQLBindCol (lake_cursor, 1, SQL_C_SLONG,
        &lake_perimeter, 0, &length_ind);

/* Outer loop:
 * get the island ids and the number of lakes (interior rings).*/
while (1)
{
    /* Fetch an island.*/
    rc = SQLFetch (island_cursor);
    if (rc == SQL_NO_DATA)
        break;
    else
        returncode_check(NULL, hstmt, rc, "SQLFetch");

    /* Inner loop: for this island,
     * get the perimeter of all its lakes (interior rings). */
    for (total_perimeter = 0, lake_number = 1;
        lake_number <= num_lakes;
        lake_number++)
    {
        rc = SQLExecute (lake_cursor);
        rc = SQLFetch (lake_cursor);
        total_perimeter += lake_perimeter;
        SQLFreeStmt (lake_cursor, SQL_CLOSE);
    }

    /* Display the island ID and the total perimeter of its lakes.*/
    printf ("Island ID = %d, Total lake perimeter = %d\n",
            island_id, total_perimeter);
}

SQLFreeStmt (lake_cursor, SQL_DROP);
SQLFreeStmt (island_cursor, SQL_DROP);

```

The ST_Intersection() function

The **ST_Intersection()** function takes two **ST_Geometry** objects and returns the intersection set as an **ST_Geometry** object. If the two objects do not intersect, the return value is an empty geometry.

Syntax

```
ST_Intersection(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

ST_Geometry

Example

The fire marshal must obtain the areas of the hospitals, schools, and nursing homes intersected by the radius of a possible hazardous waste contamination.

The sensitive areas are stored in the **sensitive_areas** table that is created with the CREATE TABLE statement that follows. The **zone** column defined as an ST_Polygon type stores the outline of each of the sensitive areas:

```
CREATE TABLE sensitive_areas (id      integer,
                               name    varchar(128),
                               size    float,
                               type    varchar(10),
                               zone    ST_Polygon);
```

The hazardous sites are stored in the **hazardous_sites** table created with the CREATE TABLE statement that follows. The **location** column, defined as an ST_Point type, stores a location that is the geographic center of each hazardous site:

```
CREATE TABLE hazardous_sites (site_id integer,
                                name     varchar(40),
                                location ST_Point);
```

The **ST_Buffer()** function generates a five-mile buffer surrounding the hazardous waste site locations. The **ST_Intersection()** function generates polygons from the intersection of the buffered hazardous waste sites and the sensitive areas. The **ST_Area()** function returns the intersection polygons' area, which is summarized for all hazardous sites by the SUM operator. The GROUP BY clause directs the query to aggregate the intersection areas by hazardous waste site ID:

```
SELECT hs.site_id, SUM(ST_Area(ST_Intersection(sa.zone,
        ST_Buffer(hs.location,(5 * 5280))))::ST_MultiPolygon))
FROM sensitive_areas sa, hazardous_sites hs
GROUP BY hs.site_id;

site_id      (sum)
102 87000000.00000
59 77158581.63280
```

In the following figure, the circles represent the five-mile buffer polygons surrounding the hazardous waste sites. The intersection of these buffer polygons with the sensitive area polygons produces three polygons: the hospital in the upper left-hand corner is intersected twice, while the school in the lower right-hand corner is intersected only once.

Figure 8-8. Using the *ST_Intersection* function

Related reference:

“The *ST_Intersection()* function” on page 7-7

The *ST_Intersects()* function

The *ST_Intersects()* function returns t (TRUE) if the intersection of two geometries does not result in an empty set; otherwise, returns f (FALSE).

Syntax

ST_Intersects (g1 *ST_Geometry*, g2 *ST_Geometry*)

Return type

BOOLEAN

Example

The fire marshal wants a list of sensitive areas within a five-mile radius of a hazardous waste site.

The sensitive areas are stored in the following **sensitive_areas** table. The **zone** column is defined as an *ST_Polygon* type and stores the outline of the sensitive areas:

```
CREATE TABLE sensitive_areas (id      integer,
                              name    varchar(128),
                              size    float,
                              type    varchar(10),
                              zone    ST_Polygon);
```

The hazardous sites are stored in the **hazardous_sites** table created with the *CREATE TABLE* statement that follows. The **location** column, defined as an *ST_Point* type, stores the geographic center of each hazardous site:

```
CREATE TABLE hazardous_sites (site_id integer,
                               name     varchar(40),
                               location ST_Point);
```

The query returns a list of sensitive-area and hazardous-site names for sensitive areas that intersect the five-mile buffer radius of the hazardous sites:

```
SELECT sa.name, hs.name
       FROM sensitive_areas sa, hazardous_sites hs
       WHERE ST_Intersects(ST_Buffer(hs.location,(5 * 5280)),sa.zone);
```

```
name Johnson County Hospital
name W. H. Kleenare Chemical Repository
```

```
name Johnson County Hospital
name Landmark Industrial
```

```
name Summerhill Elementary School
name Landmark Industrial
```

Related reference:

“The ST_Intersects() function” on page 7-2

“The ST_Intersects() function” on page 7-17

The ST_Is3D() function

The SE_Is3d() function returns t (TRUE) if the ST_Geometry object has three-dimensional coordinates; otherwise, returns f (FALSE).

Properties of geometries are described in “Properties of spatial data types” on page 2-1.

Syntax

```
ST_Is3D(g1 ST_Geometry)
```

Return type

BOOLEAN

Example

The **threed_test** table is created with INTEGER **gid** and **g1** ST_Geometry columns:

```
CREATE TABLE threed_test (gid smallint,
                          g1 ST_Geometry);
```

The following INSERT statements insert two points into the **threed_test** table. The first point does not contain Z coordinates, while the second does:

```
INSERT INTO threed_test VALUES(
    1, ST_PointFromText('point (10 10)',1000)
);
```

```
INSERT INTO threed_test VALUES(
    1, ST_PointFromText('point z(10.92 10.12 5)',1000)
);
```

The query lists the contents of the **gid** column with the results of the SE_Is3d function. The function returns a 0 for the first row, which does not have a Z coordinate, and a 1 for the second row, which does:

```

SELECT gid, ST_Is3D (g1) is_it_3d from threed_test;

gid is_it_3d
-----
1         f
1         t

```

The ST_IsClosed() function

The **ST_IsClosed()** function takes an **ST_LineString** or **ST_MultiLineString** and returns **t** (TRUE) if it is closed; otherwise, it returns **f** (FALSE).

Properties of geometries are described in “Properties of spatial data types” on page 2-1.

Syntax

```

ST_IsClosed(ln1 ST_LineString)
ST_IsClosed(mln1 ST_MultiLineString)

```

Return type

BOOLEAN

Example

The **closed_linestring** table is created with a single **ST_LineString** column:

```

CREATE TABLE closed_linestring (ln1 ST_LineString);

```

The following **INSERT** statements insert two records into the **closed_linestring** table. The first record is not a closed linestring, while the second is:

```

INSERT INTO closed_linestring VALUES(
  ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)', 1000)
);

INSERT INTO closed_linestring VALUES(
  ST_LineFromText('linestring (10.02 20.01,11.92 35.64,25.02 34.15,
  19.15 33.94,10.02 20.01)',1000)
);

```

The query returns the results of the **ST_IsClosed()** function. The first row returns a 0 because the linestring is not closed, while the second row returns a 1 because the linestring is closed.

```

SELECT ST_IsClosed(ln1) Is_it_closed
FROM closed_linestring;

is_it_closed
-----
f
t

```

The **closed_mlinestring** table is created with a single **ST_MultiLineString** column:

```

CREATE TABLE closed_mlinestring (mln1 ST_MultiLineString);

```

The following **INSERT** statements insert an **ST_MultiLineString** record that is not closed and another that is:

```

INSERT INTO closed_mlinestring VALUES(
  ST_MLineFromText('multilinestring ((10.02 20.01,10.32 23.98,
  11.92 25.64),(9.55 23.75,15.36 30.11))',1000)
);

```

```

INSERT INTO closed_mlinestring VALUES(
  ST_MLineFromText('multilinestring ((10.02 20.01,11.92 35.64,
25.02 34.15,19.15 33.94,10.02 20.01),(51.71 21.73,73.36 27.04,
71.52 32.87,52.43 31.90,51.71 21.73))',1000)
);

```

The query lists the results of the **ST_IsClosed()** function. The first row returns 0 because the multilinestring is not closed. The second row returns 1 because the multilinestring stored in the **mln1** column is closed. A multilinestring is closed if all of its linestring elements are closed:

```

SELECT ST_IsClosed(mln1) Is_it_closed
FROM cTosed_mlinestring;

```

```

is_it_closed
           f
           t

```

The ST_IsEmpty() function

The **ST_IsEmpty()** function returns t (TRUE) if the geometry is empty; otherwise, returns f (FALSE).

See a description of properties of geometries in “Properties of spatial data types” on page 2-1.

Syntax

```
ST_IsEmpty(g1 ST_Geometry)
```

Return type

BOOLEAN

Example

The CREATE TABLE statement below creates the **empty_test** table with geotype, which stores the data type of the subclasses that are stored in the **g1** ST_Geometry column:

```

CREATE TABLE empty_test (geotype varchar(20),
                          g1      ST_Geometry);

```

The following INSERT statements insert two records each for the geometry subclasses: point, linestring, and polygon; one record is empty and one is not:

```

INSERT INTO empty_test VALUES(
  'Point', ST_PointFromText('point (10.02 20.01)',1000)
);

INSERT INTO empty_test VALUES(
  'Point', ST_PointFromText('point empty',1000)
);

INSERT INTO empty_test VALUES(
  'Linestring',
  ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)',1000)
);

INSERT INTO empty_test VALUES(
  'Linestring',
  ST_LineFromText('linestring empty',1000)
);

```

```

);
INSERT INTO empty_test VALUES(
  'Polygon',
  ST_PolyFromText('polygon ((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01))',1000)
);
INSERT INTO empty_test VALUES(
  'Polygon',
  ST_PolyFromText('polygon empty',1000)
);

```

The query returns the geometry type from the **geotype** column and the results of the **ST_IsEmpty()** function:

```

SELECT geotype, ST_IsEmpty(g1) Is_it_empty
FROM empty_test

```

geotype	is_it_empty
Point	f
Point	t
Linestring	f
Linestring	t
Polygon	f
Polygon	t

The ST_IsMeasured() function

The **ST_IsMeasured()** function returns t (TRUE) if the ST_Geometry object has measures; otherwise, returns f (FALSE).

Properties of geometries are described in “Properties of spatial data types” on page 2-1.

Syntax

```

ST_IsMeasured(g1 ST_Geometry)

```

Return type

BOOLEAN

Example

The **measure_test** table is created with two columns: a SMALLINT column, **gid**, which uniquely identifies rows, and **g1**, an ST_Geometry column, which stores the ST_Point geometries:

```

CREATE TABLE measure_test (gid smallint,
                             g1 ST_Geometry);

```

The following INSERT statements insert two records into the **measure_test** table. The first record stores a point that does not have a measure, while the second record does have a measure value:

```

INSERT INTO measure_test VALUES(
  1,
  ST_PointFromText('point (10 10)',1000)
);

```

```
INSERT INTO measure_test VALUES(
    2,
    ST_PointFromText('point m (10.92 10.12 5)',1000)
);
```

The query lists the **gid** column and the results of the **ST_IsMeasured()** function. The **ST_IsMeasured()** function returns a 0 for the first row because the point does not have a measure; it returns a 1 for the second row because the point does have measures:

```
SELECT gid,ST_IsMeasured(g1) Has_measures
FROM measure_test;
```

gid	has_measures
1	f
2	t

The ST_IsRing() function

The **ST_IsRing()** function takes an **ST_LineString** and returns t (TRUE) if it is a ring (that is, the **ST_LineString** is closed and simple); otherwise, it returns f (FALSE).

Properties of geometries are described in “Properties of spatial data types” on page 2-1.

Syntax

```
ST_IsRing(ln1 ST_LineString)
```

Return type

BOOLEAN

Example

The **ring_linestring** table is created with the SMALLINT column **gid** and the **ST_LineString** column **ln1**:

```
CREATE TABLE ring_linestring (gid smallint,
    ln1 ST_LineString);
```

The following INSERT statements insert three linestrings into the **ln1** column. The first row contains a linestring that is not closed and is not a ring. The second row contains a closed and simple linestring that is a ring. The third row contains a linestring that is closed, but not simple, because it intersects its own interior. It is also not a ring:

```
INSERT INTO ring_linestring VALUES(
    1,
    ST_LineFromText('linestring (10.02 20.01,10.32 23.98,11.92 25.64)', 1000)
);
```

```
INSERT INTO ring_linestring VALUES(
    2,
    ST_LineFromText('linestring (10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94, 10.02 20.01)', 1000)
);
```

```
INSERT INTO ring_linestring VALUES(
```

```

3,
ST_LineFromText('linestring (15.47 30.12,20.73 22.12,10.83
14.13,16.45 17.24,21.56 13.37,11.23 22.56,19.11 26.78,15.47 30.12)', 1000)
);

```

The query returns the results of the **ST_IsRing()** function. The first and third rows return 0 because the linestrings are not rings, while the second row returns 1 because it is a ring:

```

SELECT gid, ST_IsRing(1nl) Is_it_a_ring
FROM ring_linestring;

```

gid	is_it_a_ring
1	f
2	t
3	f

The ST_IsSimple() function

The **ST_IsSimple()** function returns t (TRUE) if the geometry object is simple; otherwise, it returns f (FALSE). Properties of geometries are described in “Properties of spatial data types” on page 2-1.

Syntax

```

ST_IsSimple (g1 ST_Geometry)

```

Return type

BOOLEAN

Example

The table **issimple_test** is created with two columns. The **pid** column is a SMALLINT containing the unique identifier for each row. The **g1** ST_Geometry column stores the simple and nonsimple geometry samples:

```

CREATE TABLE issimple_test (pid smallint,
                             g1 ST_Geometry);

```

The following INSERT statements insert two records into the **issimple_test** table. The first is a simple linestring because it does not intersect its interior. The second is non-simple because it does intersect its interior:

```

INSERT INTO issimple_test VALUES(
1,
ST_LineFromText('linestring (10 10, 20 20, 30 30)',1000)
);

INSERT INTO issimple_test VALUES(
2,
ST_LineFromText('linestring (10 10,20 20,20 30,10 30,10 20,20 10)',1000)
);

```

The query returns the results of the **ST_IsSimple()** function. The first record returns t because the linestring is simple, while the second record returns f because the linestring is not simple:

```

SELECT pid, ST_IsSimple(g1) Is_it_simple
FROM issimple_test;

```

```
pid is_it_simple
1          t
2          f
```

The ST_IsValid() function

The **ST_IsValid()** function takes an **ST_Geometry** and returns **t** (TRUE) if it is topologically correct; otherwise it returns **f** (FALSE). Properties of geometries are described in “Properties of spatial data types” on page 2-1.

The IBM Informix Spatial DataBlade Module validates spatial data before accepting it, so **ST_IsValid()** always returns TRUE. This function may be used to validate spatial data supplied by other implementations of the OpenGIS spatial data specification.

Syntax

```
ST_IsValid(g ST_Geometry)
```

Return type

BOOLEAN

The ST_Length() function

The **ST_Length()** function returns the length of an **ST_LineString** or **ST_MultiLineString**.

Syntax

```
ST_Length(ln1 ST_LineString)
ST_Length(mln1 ST_MultiLineString)
```

Return type

DOUBLE PRECISION

Example

A local ecologist studying the migratory patterns of the salmon population in the county's waterways wants the length of all stream and river systems within the county.

The **waterways** table is created with the **ID** and **name** columns that identify each stream and river system stored in the table. The **water** column is a multilinestring, because the river and stream systems are often an aggregate of several linestrings:

```
CREATE TABLE waterways (id      integer,
                        name    varchar(128),
                        water   ST_MultiLineString);
```

The query returns the name of each system along with the length of the system generated by the length function:

```
SELECT name, ST_Length(water) Length
FROM waterways;
```

```
name      Fedders creek
length   175853.9869703
```

The following figure displays the river and stream systems that lie within the county boundary.

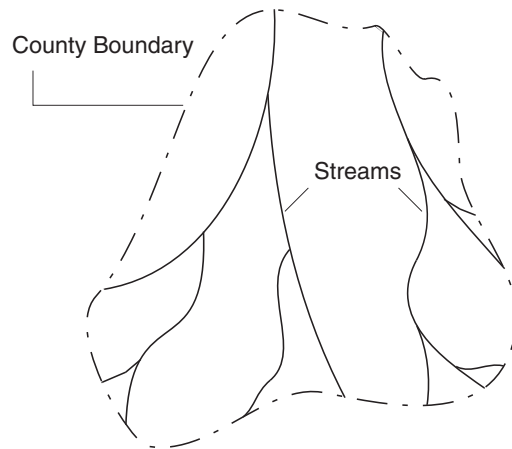

Figure 8-9. Stream and river systems

The ST_LineFromGML() function

The `ST_LineFromGML()` function takes a GML2 or GML3 string representation of an `ST_LineString` and an optional spatial reference ID and returns a polyline object.

Syntax

```
ST_LineFromGML(gmlstring lvarchar)
ST_LineFromGML(gmlstring lvarchar, SRID integer)
```

Return type

`ST_LineString`

Example

The `gml_linetest` table is created with the `SMALLINT` column `gid` and the `ST_LineString` column `ln1`:

```
CREATE TABLE gml_linetest (gid smallint, ln1 ST_LineString);

INSERT INTO gml_linetest VALUES (1, ST_LineFromGML('<gml:LineString>
<gml:posList> -110.45 45.256 -109.48 46.46 -109.86 43.84
</gml:posList></gml:LineString>',4));
INSERT INTO gml_linetest VALUES (2, ST_LineFromGML('<gml:LineString
srsName="EPSG:4326" srsDimension="3"><gml:posList
dimension="3">-110.449999933 45.2559999343 10
-109.47999994 46.4600005499 10 -109.86000008
43.8400000201 20</gml:posList></gml:LineString>'));
INSERT INTO gml_linetest VALUES(3,ST_LineFromGML('<gml:LineString
srsName="EPSG:4326" srsDimension="4"><gml:posList
dimension="4">-110.449999933 45.2559999343 10 54
-109.47999994 46.4600005499 10 58
-109.86000008 43.8400000201 20 64 </gml:posList>
</gml:LineString>'));
```

The first record specifies a spatial reference ID of 4 (WGS84) and a default dimension of 2. The second and third records contain Z and M measures and pass the spatial reference ID through the `srsName` attribute.

Output:

```
SELECT * FROM gml_linetest;
```

```
gid 1
ln1 4 LINESTRING (-110.449999933 45.2559999343,
                  -109.47999994 46.4600000469,
                  -109.860000008 43.8400000201)
```

```
gid 2
ln1 4 LINESTRING Z (-110.449999933 45.2559999343 10,
                   -109.47999994 46.4600005499 10,
                   -109.860000008 43.8400000201 20)
```

```
gid 3
ln1 4 LINESTRING ZM (-110.449999933 45.2559999343 10 54,
                    -109.47999994 46.4600005499 10 58,
                    -109.860000008 43.8400000201 20 64)
```

The ST_LineFromKML() function

The **ST_LineFromKML()** function takes a KML LineString string and an optional spatial reference ID and returns a linestring object. A KML LineString string can contain the KML shape attributes `<extrude>`, `<tessellate>`, and `<altitudeMode>`, but they are ignored in the ST_LineString representation.

Syntax

```
ST_LineFromKML(kmlstring lvarchar)
ST_LineFromKML(kmlstring lvarchar, SRID integer)
```

Return type

ST_LineString

Example

```
EXECUTE FUNCTION ST_LineFromKML('<LineString><coordinates>-130.597293,50.678292,
                                0 -129.733457,50.190606,0 -130.509877,49.387208,
                                0 -128.801553,48.669761,0 -129.156745,47.858658,
                                0 -128.717835,47.739997,0</coordinates></LineString>',4);
```

Output:

```
(expression) 4 LINESTRING Z (-130.597292947 50.6782919759 0, -129.733456972
50.1906059982 0, -130.509877068 49.3872080751 0, -128.801553066 48.669761042 0,
-129.156744951 47.8586579701 0, -128.717834948 47.7399970362 0)
```

The SE_LineFromShape() function

The **SE_LineFromShape()** function takes a shape of type polyline and a spatial reference ID to return an ST_LineString. A polyline with only one part is appropriate as an ST_LineString, and a polyline with multiple parts is appropriate as an ST_MultiLineString (see “The SE_MLineFromShape() function” on page 8-74).

Syntax

```
SE_LineFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_LineString

Example

The **sewerlines** table is created with three columns: **sewer_id**, which uniquely identifies each sewer line; the **INTEGER class** column, which identifies the type of sewer line (generally associated with the line's capacity); and the **sewer ST_LineString** column, which stores the sewer line geometry:

```
CREATE TABLE sewerlines (sewer_id integer,
                          class      integer,
                          sewer      ST_LineString);
```

This code fragment populates the **sewerlines** table with the unique ID, class, and geometry of each sewer line:

```
/* Create the SQL insert statement to populate the sewerlines
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO sewerlines (sewer_id,class,sewer) "
        "VALUES(?, ?, SE_LineFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the sewer_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &sewer_id, 0, &pcbvalue1);

/* Bind the sewer_class to the second parameter. */
pcbvalue2 = 0;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &sewer_class, 0, &pcbvalue2);

/* Bind the sewer geometry to the third parameter. */
pcbvalue3 = sewer_shape_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, sewer_shape_len, 0,
                      sewer_shape_buf, sewer_shape_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_LineFromText() function

The **ST_LineFromText()** function takes a well-known text representation of type **ST_LineString** and a spatial reference ID and returns an **ST_LineString**.

Syntax

```
ST_LineFromText(WKT lvarchar, SRID integer)
```

Return type

ST_LineString

Example

The **linestring_test** table is created with a single **ln1 ST_LineString** column:

```
CREATE TABLE linestring_test (ln1 ST_LineString);
```

The following INSERT statement inserts an ST_LineString into the **ln1** column using the **ST_LineFromText()** function:

```
INSERT INTO linestring_test VALUES(
    ST_LineFromText('linestring(10.01 20.03,20.94 21.34,35.93 19.04)',1000)
);
```

The ST_LineFromWKB() function

The **ST_LineFromWKB()** function takes a well-known binary representation of type ST_LineString and a spatial reference ID, returning an ST_LineString.

Syntax

```
ST_LineFromWKB(wkb lvarchar, SRID integer)
```

Return type

ST_LineString

Example

The **sewerlines** table is created with three columns. The first column, **sewer_id**, uniquely identifies each sewer line. The **INTEGER class** column identifies the type of sewer line, generally associated with the line capacity. The **sewer ST_LineString** column stores the sewer line geometries:

```
CREATE TABLE sewerlines (sewer_id integer,
                        class integer,
                        sewer ST_LineString);
```

This code fragment populates the **sewerlines** table with the unique ID, class, and geometry of each sewer line:

```
/* Create the SQL insert statement to populate the sewerlines
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO sewerlines (sewer_id,class,sewer) "
        "VALUES(?, ?, ST_LineFromWKB(?, %d)", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the sewer_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &sewer_id, 0, &pcbvalue1);

/* Bind the sewer_class to the second parameter. */
pcbvalue2 = 0;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &sewer_class, 0, &pcbvalue2);

/* Bind the sewer geometry to the third parameter. */
pcbvalue3 = sewer_wkb_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, sewer_wkb_len, 0,
                      sewer_wkb_buf, sewer_wkb_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_LocateAlong() function

The **ST_LocateAlong()** function takes a geometry object and a measure to return as an ST_MultiPoint the set of points found having that measure.

Syntax

```
ST_LocateAlong(g1 ST_Geometry, m1 double precision)
```

Return type

ST_Geometry

Example

The **locatealong_test** table is created with two columns: the **gid** column uniquely identifies each row, and the **g1** ST_Geometry column stores sample geometry:

```
CREATE TABLE locatealong_test (gid integer,  
                                g1 ST_Geometry);
```

The following INSERT statements insert two rows. The first is a multilinestring, while the second is a multipoint:

```
INSERT INTO locatealong_test VALUES(  
    1,  
    ST_MLineFromText('multilinestring m ((10.29 19.23 5,23.82 20.29  
6,30.19 18.47 7,45.98 20.74 8),(23.82 20.29 6,30.98 23.98 7,42.92  
25.98 8))', 1000)  
);
```

```
INSERT INTO locatealong_test VALUES(  
    2,  
    ST_MPointFromText('multipoint m (10.29 19.23 5,23.82 20.29  
6,30.19 18.47 7,45.98 20.74 8,23.82 20.29 6,30.98 23.98 7,42.92  
25.98 8)', 1000)  
);
```

In this query, the **ST_LocateAlong()** function finds points whose measure is 6.5. The first row returns an ST_MultiPoint containing two points. However, the second row returns an empty point. For linear features (geometry with a dimension greater than 0), **ST_LocateAlong()** can interpolate the point, but for multipoints the target measure must match exactly:

```
SELECT gid, SE_locatealong(g1,6.5) Geometry  
FROM locatealong_test;
```

```
gid      1  
geometry 1000 MULTIPOINT M (27.005 19.38 6.5, 27.4 22.135 6.5)  
  
gid      2  
geometry 1000 POINT M EMPTY
```

In this query, the **ST_LocateAlong()** function returns a multipoint for both rows. The target measure of 7 matches measures in the multilinestring and multipoint source data:

```
SELECT gid, SE_locatealong(g1,7) Geometry  
FROM locatealong_test;
```

```
gid      1  
geometry 1000 MULTIPOINT M (30.19 18.47 7, 30.98 23.98 7)
```

```
gid          2
geometry     1000 MULTIPOINT M (30.19 18.47 7, 30.98 23.98 7)
```

The ST_LocateBetween() function

The **ST_LocateBetween()** function takes an ST_Geometry object and two measure locations and returns an ST_Geometry that represents the set of disconnected paths between the two measure locations.

Syntax

```
ST_LocateBetween(g1 ST_Geometry, fm double precision, tm double precision)
```

Return type

ST_Geometry

Example

The `locatebetween_test` table is created with two columns: the **gid** INTEGER column uniquely identifies each row, while the **g1** ST_MultiLineString stores the sample geometry:

```
CREATE TABLE locatebetween_test (gid integer, g1 ST_Geometry);
```

The following INSERT statements insert two rows into the `locatebetween_test` table. The first row is an ST_MultiLineString and the second is an ST_MultiPoint:

```
INSERT INTO locatebetween_test VALUES(
  1,
  ST_MLineFromText('multilinestring m ((10.29 19.23 5,23.82 20.29
6, 30.19 18.47 7,45.98 20.74 8),(23.82 20.29 6,30.98 23.98 7,42.92
25.98 8)'),1000)
);
```

```
INSERT INTO locatebetween_test VALUES(
  2,
  ST_MPointFromText('multipoint m (10.29 19.23 5,23.82 20.29
6,30.19 18.47 7,45.98 20.74 8,23.82 20.29 6,30.98 23.98 7,42.92
25.98 8)', 1000)
);
```

In the query, the **ST_LocateBetween** function locates measures that lie between 6.5 and 7.5, inclusively. The first row returns an ST_MultiLineString containing several linestrings. The second row returns an ST_MultiPoint because the source data was ST_MultiPoint. When the source data has a dimension of 0 (point or multipoint), an exact match is required:

```
SELECT gid, ST_LocateBetween(g1,6.5,7.5) Geometry
FROM locatebetween_test;
```

```
gid          1
geometry     1000 MULTILINESTRING M ((27.005 19.38 6.5, 30.19 18.47
7, 38.085 19.6
05 7.5),(27.4 22.135 6.5, 30.98 23.98 7, 36.95 24.98 7.5))
```

```
gid          2
geometry     1000 MULTIPOINT M (30.19 18.47 7, 30.98 23.98 7)
```

The ST_M() function

The **ST_M()** function returns the measure value of a point.

Syntax

```
ST_M(p1 ST_Point)
```

Return type

DOUBLE PRECISION

Example

The **m_test** table is created with the **gid** INTEGER column, which uniquely identifies the row, and the **pt1** ST_Point column that stores the sample geometry:

```
CREATE TABLE m_test (gid integer,  
                    pt1 ST_Point);
```

The following INSERT statements insert a point with measures and a point without measures:

```
INSERT INTO m_test VALUES(  
    1,  
    ST_PointFromText('point (10.02 20.01)', 1000)  
);  
  
INSERT INTO m_test VALUES(  
    2,  
    ST_PointFromText('point zm (10.02 20.01 5.0 7.0)', 1000)  
);
```

In this query, the **ST_M()** function lists the measure values of the points. Because the first point does not have measures, the **ST_M()** function returns NULL:

```
SELECT gid, ST_M(pt1) The_measure  
FROM m_test;
```

```
gid    the_measure  
-----  
1  
2 7.0000000000000
```

The ST_MaxM() and ST_MinM() functions

The **ST_MaxM()** and **ST_MinM()** functions return the maximum and minimum measure values of a geometry.

Syntax

```
ST_MaxM(ST_Geometry)
```

```
ST_MinM(ST_Geometry)
```

Return type

DOUBLE PRECISION

The ST_MaxX() and ST_MinX() functions

The **ST_MaxX()** and **ST_MinX()** functions return the maximum and minimum X coordinates of a geometry.

Syntax

ST_MaxX(ST_Geometry)

ST_MinX(ST_Geometry)

Return type

DOUBLE PRECISION

The ST_MaxY() and ST_MinY() functions

The **ST_MaxY()** and **ST_MinY()** functions return the maximum and minimum Y coordinates of a geometry.

Syntax

ST_MaxY(ST_Geometry)

ST_MinY(ST_Geometry)

Return type

DOUBLE PRECISION

The ST_MaxZ() and ST_MinZ() functions

The **ST_MaxZ()** and **ST_MinZ()** functions return the maximum and minimum Z coordinates of a geometry.

Syntax

ST_MaxZ(ST_Geometry)

ST_MinZ(ST_Geometry)

Return type

DOUBLE PRECISION

The SE_MetadataInit() function

The **SE_MetadataInit()** function reinitializes the spatial reference system large object and memory cache.

For computational efficiency and to allow spatial data type functions to be executed in parallel, the contents of the **spatial_references** table are kept in both a smart large object and a memory cache. If these copies become corrupt or unreadable, one of the following errors is raised:

- USE48 SE_Metadata lohandle file not found, unreadable, or corrupt.
- USE51 SE_Metadata smart blob is corrupt or unreadable.
- USE52 SE_Metadata memory cache is locked.

Execute the **SE_MetadataInit()** function to reinitialize the spatial reference system smart large object and memory cache.

Syntax

SE_MetadataInit()

Return type

The text string OK, if the function was successfully executed

Example

```
execute function SE_MetadataInit();
```

Related reference:

“Resolve problems with SE_MetadataInit()” on page 5-1

The SE_Midpoint() function

The **SE_Midpoint()** function determines the midpoint of a linestring. The midpoint is defined as that point which is equidistant from both endpoints of a linestring, measuring distance along the linestring.

If the input linestring has Z values or measures, the Z value or measure of the midpoint are computed by linear interpolation between the adjacent vertices.

Syntax

```
SE_Midpoint (ln1 ST_LineString)
```

Return type

ST_Point

The ST_MLineFromGML() function

The **ST_MLineFromGML()** function takes a GML2 or GML3 string representation of an ST_MultiLineString and an optional spatial reference ID and returns a multipart polyline object.

Syntax

```
ST_MLineFromGML(gmlstring lvarchar)  
ST_MLineFromGML(gmlstring lvarchar, SRID integer)
```

Return type

ST_MultiLineString

Example

The **gml_linetest** table is created with the SMALLINT column **gid** and the ST_MultiLineString column **ln1**:

```
CREATE TABLE gml_linetest(gid smallint, ln1 ST_MultiLineString);  
  
INSERT INTO gml_linetest VALUES (1, ST_MLineFromGML('<gml:MultiLineString>  
<gml:LineStringMember><gml:LineString><gml:posList>-110.45 45.256  
-109.48 46.46 -109.86 43.84</gml:posList></gml:LineString>  
</gml:LineStringMember><gml:LineStringMember><gml:LineString>  
<gml:posList>-99.45 33.256 -99.48 36.46 -99.86 33.84</gml:posList>  
</gml:LineString></gml:LineStringMember></gml:MultiLineString>',4));  
  
INSERT INTO gml_linetest VALUES (2, ST_MLineFromGML('<gml:MultiLineString  
srsName="EPSG:4326" srsDimension="3"><gml:LineStringMember>  
<gml:LineString srsName="EPSG:4326" srsDimension="3"><gml:posList  
dimension="3">-110.449999933 45.2559999343 10 -109.47999994  
46.4600005499 10 -109.86000008 43.8400000201 20</gml:posList>
```

```

        </gml:LineString></gml:LineStringMember><gml:LineStringMember>
        <gml:LineString srsName="EPSG:4326" srsDimension="3"><gml:posList
        dimension="3">-99.45 33.256 10 -99.48 36.46 10 -99.86 33.84 20
        </gml:posList></gml:LineString></gml:LineStringMember>
    </gml:MultiLineString>');
INSERT INTO gml_linetest VALUES (3, ST_MLineFromGML('<gml:MultiLineString
srsName="EPSG:4326" srsDimension="4"><gml:LineStringMember>
<gml:LineString srsName="EPSG:4326" srsDimension="4"><gml:posList
dimension="4">-110.449999933 45.2559999343 10 54 -109.479999994
46.4600005499 10 58 -109.860000008 43.8400000201 20 64</gml:posList>
</gml:LineString></gml:LineStringMember><gml:LineStringMember>
<gml:LineString srsName="EPSG:4326" srsDimension="4"><gml:posList
dimension="4">-99.45 33.256 10 54 -99.48 36.46 10 58 -99.86 33.84 20 64
</gml:posList></gml:LineString></gml:LineStringMember>
</gml:MultiLineString>'));

```

The first record specifies a spatial reference ID of 4 (WGS84) and a default dimension of 2. The second and third records contain Z and M measures and pass the spatial reference ID through the srsName attribute.

Output:

```
SELECT * FROM gml_linetest;
```

```

3 row(s) retrieved.

The ST_MLineFromKML() function

The **ST_MLineFromKML()** function takes a KML MultiLineString string and an optional spatial reference ID and returns a multipart polyline object. A KML MultiLineString string can contain the KML shape attributes <extrude>, <tessellate>, and <altitudeMode>, but they are ignored in the ST_MultiLineString representation.

Syntax

```

ST_MLineFromKML(kmlstring lvarchar)
ST_MLineFromKML(kmlstring lvarchar, SRID integer)

```

Return type

ST_MultiLineString

Example

```
EXECUTE FUNCTION ST_MLineFromKML(<MultiGeometry>
  <LineString>
    <coordinates>
      -122.4425587930444,37.80666418607323,0
      -122.4428379594768,37.80663578323093,0
    </coordinates>
  </LineString>
  <LineString>
    <coordinates>
      -122.4425509770566,37.80662588061205,0
      -122.4428340530617,37.8065999493009,0
    </coordinates>
  </LineString>
</MultiGeometry>,4);
```

The SE_MLineFromShape() function

The **SE_MLineFromShape()** function creates an **ST_MultiLineString** from a shape of type **polyline** and a spatial reference ID. A **polyline** with only one part is appropriate as an **ST_LineString** (see “The **SE_LineFromShape()** function” on page 8-65) and a **polyline** with multiple parts is appropriate as an **ST_MultiLineString**.

Syntax

```
SE_MLineFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_MultiLineString

Example

The **waterways** table is created with the **ID** and **name** columns that identify each stream and river system stored in the table. The **water** column is an **ST_MultiLineString** because the river and stream systems are often an aggregate of several linestrings:

```
CREATE TABLE waterways (id      integer,
                        name    varchar(128),
                        water    ST_MultiLineString);
```

This code fragment populates the **waterways** table with a unique ID, a name, and a **water** multilinestring:

```
/* Create the SQL insert statement to populate the waterways
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO waterways (id,name,water) "
        "VALUES(?, ?, ST_MLineFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &id, 0, &pcbvalue1);

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
```

```

        SQL_CHAR, name_len, 0,
        name, name_len, &pcbvalue2);

/* Bind the water geometry to the third parameter. */
pcbvalue3 = water_shape_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
        SQL_INFX_UDT_LVARCHAR, water_shape_len, 0,
        water_shape_buf, water_shape_len, &pcbvalue3);
/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The ST_MLineFromText() function

The **ST_MLineFromText()** function takes a well-known text representation of type **ST_MultiLineString** and a spatial reference ID and returns an **ST_MultiLineString**.

Syntax

```
ST_MLineFromText(wkt lvarchar, SRID integer)
```

Return type

ST_MultiLineString

Example

The **mlinestring_test** is created with the **gid** SMALLINT column that uniquely identifies the row and the **m1** **ST_MultiLineString** column:

```
CREATE TABLE mlinestring_test (gid smallint,
        m1 ST_MultiLineString);
```

The following **INSERT** statement inserts the **ST_MultiLineString** with the **ST_MLineFromText()** function:

```
INSERT INTO mlinestring_test VALUES(
    1,
    ST_MLineFromText('multilinestring((10.01 20.03,10.52
40.11,30.29 41.56,31.78 10.74),(20.93 20.81, 21.52 40.10))', 1000)
)
```

The ST_MLineFromWKB() function

The **ST_MLineFromWKB()** function creates an **ST_MultiLineString** from a well-known binary representation of type **ST_MultiLineString** and a spatial reference ID.

Syntax

```
ST_MLineFromWKB(WKB lvarchar, SRID integer)
```

Return type

ST_MultiLineString

Example

The **waterways** table is created with the **ID** and **name** columns that identify each stream and river system stored in the table. The **water** column is an **ST_MultiLineString** because the river and stream systems are often an aggregate of several linestrings:

```
CREATE TABLE waterways (id      integer,
                        name    varchar(128),
                        water   ST_MultiLineString);
```

This code fragment populates the **waterways** table with a unique ID, a name, and a **water** ST_MultiLineString:

```
/* Create the SQL insert statement to populate the waterways
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO waterways (id,name,water) "
        "VALUES(?, ?, ST_MlineFromWKB(?, %d)", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &id, 0, &pcbvalue1);

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, name_len, 0,
                      name, name_len, &pcbvalue2);

/* Bind the water geometry to the third parameter. */
pcbvalue3 = water_wkb_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, water_wkb_len, 0,
                      water_wkb_buf, water_wkb_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_MPointFromGML() function

The **ST_MPointFromGML()** function takes a GML2 or GML3 string representation of an ST_MultiPoint and an optional spatial reference ID and returns a polygon object.

Syntax

```
ST_MPointFromGML(gmlstring lvarchar)
ST_MPointFromGML(gmlstring lvarchar, SRID integer)
```

Return type

ST_MultiPoint

Example

The **gml_pointtest** table is created with the SMALLINT column **gid** and the ST_MultiPoint column **mpt1**:

```
CREATE TABLE gml_pointtest(gid smallint, mpt1 ST_MultiPoint);

INSERT INTO gml_pointtest VALUES (1, ST_MPointFromGML('<gml:MultiPoint>
<gml:PointMember><gml:Point><gml:pos>-110.45 45.256</gml:pos>
</gml:Point></gml:PointMember><gml:PointMember><gml:Point>
<gml:pos>-99.45 33.256</gml:pos></gml:Point></gml:PointMember>
</gml:MultiPoint>',4));
```

```
INSERT INTO gml_pointtest VALUES (2, ST_MPointFromGML('<gml:MultiPoint
srsName="EPSG:4326" srsDimension="3"><gml:PointMember><gml:Point
srsName="EPSG:4326" srsDimension="3"><gml:pos>-110.449999933
45.2559999343 10</gml:pos></gml:Point></gml:PointMember>
<gml:PointMember><gml:Point srsName="EPSG:4326" srsDimension="3">
<gml:pos>-99.86 33.84 20</gml:pos></gml:Point></gml:PointMember>
</gml:MultiPoint>'));
```

```
INSERT INTO gml_pointtest VALUES (3, ST_MPointFromGML('<gml:MultiPoint
srsName="EPSG:4326" srsDimension="4"><gml:PointMember><gml:Point
srsName="EPSG:4326" srsDimension="4"><gml:pos>-109.47999994
46.4600005499 10 58</gml:pos></gml:Point></gml:PointMember>
<gml:PointMember><gml:Point srsName="EPSG:4326" srsDimension="4">
<gml:pos>-99.45 33.256 10 54</gml:pos></gml:Point></gml:PointMember>
</gml:MultiPoint>'));
```

The first record specifies a spatial reference ID of 4 (WGS84) and a default dimension of 2. The second and third records contain Z and M measures and pass the spatial reference ID through the srsName attribute.

Output:

```
SELECT * FROM gml_pointtest;
```

```
gid 1
mpt1 4 MULTIPOINT (-110.449999933 45.2559999343, -99.4499999329 33.2559999343)
```

```
gid 2
mpt1 4 MULTIPOINT Z (-110.449999933 45.2559999343 10, -99.8600000805 33.840000
0201 20)
```

```
gid 3
mpt1 4 MULTIPOINT ZM (-109.47999994 46.4600005499 10 58, -99.4499999329 33.255
9999343 10 54)
```

3 row(s) retrieved.

The ST_MPointFromKML() function

The **ST_MPointFromKML()** function takes a KML MultiGeometry and Point combination and an optional spatial reference ID and returns a multipoint object. A Point string can contain the elements of <coordinates>, <extrude>, <tessellate>, and <altitudeMode>, but they are ignored.

Syntax

```
ST_MPointFromKML(kmlstring lvarchar)
ST_MPointFromKML(kmlstring lvarchar, SRID integer)
```

Return type

ST_MultiPoint

Example

```
EXECUTE FUNCTION ST_MPointFromKML('<MultiGeometry><Point><coordinates>
-122.365662,37.826988, 0</coordinates></Point><Point>
<coordinates>-122.365038,37.82655,0</coordinates>
</Point></MultiGeometry>',4);
```

Output:

```
4 MULTIPOINT Z (-122.365662056 37.8269879529 0, -122.36503794
37.8265500822 0)
```

The SE_MPointFromShape() function

The **SE_MPointFromShape()** function takes a shape of type multipoint and a spatial reference ID to return an ST_MultiPoint.

Syntax

```
SE_MPointFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_MultiPoint

Example

The **species_sitings** table is created with three columns. The **species** and **genus** columns uniquely identify each row, while the **sitings** ST_MultiPoint stores the locations of the species sitings:

```
CREATE TABLE species_sitings (species varchar(32),
                               genus  varchar(32),
                               sitings ST_MultiPoint);
```

This code fragment populates the **species_sitings** table:

```
/* Create the SQL insert statement to populate the species_sitings
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO species_sitings (species,genus,sitings) "
        "VALUES(?, ?, SE_MpointFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the species to the first parameter. */
pcbvalue1 = species_len;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, species_len, 0,
                      species, species_len, &pcbvalue1);

/* Bind the genus to the second parameter. */
pcbvalue2 = genus_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, genus_len, 0,
                      genus, genus_len, &pcbvalue2);

/* Bind the sitings geometry to the third parameter. */
pcbvalue3 = sitings_shape_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, sitings_shape_len, 0,
                      sitings_shape_buf, sitings_shape_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_MPointFromText() function

The **ST_MPointFromText()** function creates an ST_MultiPoint from a well-known text representation of type ST_MultiPoint and a spatial reference ID.

Syntax

```
ST_MPointFromText(WKT lvarchar, SRID integer)
```

Return type

ST_MultiPoint

Example

The **multipoint_test** table is created with the single ST_MultiPoint **mpt1** column:

```
CREATE TABLE multipoint_test (gid smallint,  
                               mpt1 ST_MultiPoint);
```

The following INSERT statement inserts a multipoint into the **mpt1** column using the **ST_MPointFromText()** function:

```
INSERT INTO multipoint_test VALUES(  
    1,  
    ST_MPointFromText('multipoint(10.01 20.03,10.52 40.11,30.29  
41.56,31.78 10.74)',1000)  
);
```

The ST_MPointFromWKB() function

The **ST_MPointFromWKB()** function creates an ST_MultiPoint from a well-known binary representation of type ST_MultiPoint and a spatial reference ID.

Syntax

```
ST_MPointFromWKB (WKB lvarchar, SRID integer)
```

Return type

ST_MultiPoint

Example

The **species_sitings** table is created with three columns. The **species** and **genus** columns uniquely identify each row, while the **sitings** ST_MultiPoint stores the locations of the species sightings:

```
CREATE TABLE species_sitings (species varchar(32),  
                               genus   varchar(32),  
                               sitings ST_MultiPoint);
```

This code fragment populates the **species_sitings** table:

```
/* Create the SQL insert statement to populate the species_sitings  
 * table. The question marks are parameter markers that indicate  
 * the column values that will be inserted at run time. */  
sprintf(sql_stmt,  
        "INSERT INTO species_sitings (species,genus,sitings) "  
        "VALUES(?, ?, ST_MpointFromWKB(?, %d))", srid);  
  
/* Prepare the SQL statement for execution. */  
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);  
  
/* Bind the species to the first parameter. */  
pcbvalue1 = species_len;  
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR,  
                      SQL_CHAR, species_len, 0,  
                      species, species_len, &pcbvalue1);
```

```

/* Bind the genus to the second parameter. */
pcbvalue2 = genus_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                        SQL_CHAR, genus_len, 0,
                        genus, genus_len, &pcbvalue2);

/* Bind the sitings geometry to the third parameter. */
pcbvalue3 = sitings_wkb_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                        SQL_INFX_UDT_LVARCHAR, sitings_wkb_len, 0,
                        sitings_wkb_buf, sitings_wkb_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The ST_MPolyFromGML() function

The **ST_MPolyFromGML()** function takes a GML2 or GML3 string representation of an ST_MultiPolygon and an optional spatial reference ID and returns a multipart polygon object.

Syntax

```

ST_MPolyFromGML(gmlstring lvvarchar)
ST_MPolyFromGML(gmlstring lvvarchar, SRID integer)

```

Return type

ST_MultiPolygon

Example

The **test_multipoly** table is created with the INTEGER column **id** and the ST_MultiPolygon column **geom**:

```

CREATE TABLE test_multipoly (id INTEGER, geom ST_MultiPolygon);

INSERT INTO test_multipoly VALUES(1,ST_MPolyFromGML
('<gml:MultiPolygon srsName="EPSG:4326" srsDimension="2">
<gml:PolygonMember><gml:Polygon srsName="EPSG:4326" srsDimension="2">
<gml:exterior><gml:LinearRing><gml:posList dimension="2">
-94.36 32.49 -92.66 32.69 -92.15 32.46 -93.09 33.08 -93.37 33.19
-94.36 32.49</gml:posList></gml:LinearRing>
</gml:exterior></gml:Polygon></gml:PolygonMember>
<gml:PolygonMember><gml:Polygon srsName="EPSG:4326" srsDimension="2">
<gml:exterior><gml:LinearRing><gml:posList dimension="2">
-84.36 32.49 -82.66 32.69 -82.15 32.46 -83.09 33.08 -83.37 33.19
-84.36 32.49</gml:posList></gml:LinearRing></gml:exterior>
< /gml:Polygon></gml:PolygonMember></gml:MultiPolygon>',4));

```

This record specifies a spatial reference ID of 4 (WGS84) and both member polygons have a dimension of 2 and six sides.

Output:

```

SELECT * FROM test_multipoly;

id      1
geom    4 MULTIPOLYGON (((-94.36000000805 32.49000000536, -92.6599999799
32.6899999866, -92.1500000335 32.4600000469,
-93.0900000201 33.0800000738, -93.3700000268
33.1899999866, -94.3600000805 32.4900000536)),
((-84.3600000805 32.4900000536, -82.6599999799

```

```
32.6899999866, -82.1500000335 32.4600000469,  
-83.0900000201 33.0800000738, -83.3700000268  
33.1899999866, -84.3600000805 32.4900000536)))
```

The ST_MPolyFromKML() function

The **ST_MPolyFromKML()** function takes a MultiGeometry and Polygon combination and an optional spatial reference ID and returns a polygon object.

Syntax

```
ST_MPolyFromKML(kmlstring lvarchar)  
ST_MPolyFromKML(kmlstring lvarchar, SRID integer)
```

Return type

ST_MultiPolygon

Example

The **test_multipoly** table is created with the INTEGER column **id** and the ST_MultiPolygon column **geom**:

```
CREATE TABLE test_multipoly (id INTEGER, geom ST_MultiPolygon);  
  
INSERT INTO test_multipoly VALUES(1,ST_MPolyFromKML('<MultiGeometry>  
<Polygon><outerBoundaryIs><LinearRing><coordinates>  
-94.36,32.49 -92.65,32.68 -92.15,32.46 -93.09,33.08  
-93.37,33.18 -94.36,32.49</coordinates>  
</LinearRing></outerBoundaryIs></Polygon><Polygon>  
<outerBoundaryIs><LinearRing><coordinates>-84.36,32.49  
-82.65,32.68 -82.15,32.46 -83.09,33.08 -83.37,33.18  
-84.3600000805,32.4900000536</coordinates>  
</LinearRing></outerBoundaryIs></Polygon><  
/MultiGeometry>',4));
```

This record specifies a spatial reference ID of 4 (WGS84) and both member polygons have two dimensions and six sides.

Output:

```
SELECT * FROM test_multipoly;  
  
id      1  
geom    4 MULTIPOLYGON (((-94.3600000805 32.4900000536, -92.6599999799  
32.6899999866, -92.1500000335 32.4600000469, -93.0900000201  
33.0800000738, -93.3700000268 33.1899999866, -94.3600000805  
32.4900000536)),((-84.3600000805 32.4900000536, -82.6599999799  
32.6899999866, -82.1500000335 32.4600000469, -83.0900000201  
33.0800000738, -83.3700000268 33.1899999866, -84.3600000805  
32.4900000536)))
```

The SE_MPolyFromShape() function

The **SE_MPolyFromShape()** function takes a shape of type polygon and a spatial reference ID to return an ST_MultiPolygon.

Syntax

```
SE_MPolyFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_MultiPolygon

Example

The **lots** table stores the **lot_id**, which uniquely identifies each lot, and the **lot** multipolygon that contains the lot line geometry:

```
CREATE TABLE lots (lot_id integer,
                   lot      ST_MultiPolygon);
```

This code fragment populates the **lots** table:

```
/* Create the SQL insert statement to populate the lots table.
 * The question marks are parameter markers that indicate the
 * column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO lots (lot_id,lot)"
        "VALUES(?, SE_MpolyFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry to the second parameter. */
pcbvalue2 = lot_shape_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_shape_len, 0,
                      lot_shape_buf, lot_shape_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_MPolyFromText() function

The **ST_MPolyFromText()** function takes a well-known text representation of type ST_MultiPolygon and a spatial reference ID and returns an ST_MultiPolygon.

Syntax

```
ST_MPolyFromText(WKT lvarchar, SRID integer)
```

Return type

ST_MultiPolygon

Example

The **multipolygon_test** table is created with the single ST_MultiPolygon **mp11** column:

```
CREATE TABLE multipolygon_test (mp11 ST_MultiPolygon);
```

The following INSERT statement inserts an ST_MultiPolygon into the **mp11** column using the **ST_MPolyFromText()** function:

```

INSERT INTO multipolygon test VALUES(
    ST_MPolyFromText('multipolygon(((10.01 20.03,10.52 40.11,30.29
41.56,31.78 10.74,10.01 20.03),(21.23 15.74,21.34 35.21,28.94
35.35,29.02 16.83,21.23 15.74)),((40.91 10.92,40.56 20.19,50.01
21.12,51.34 9.81,40.91 10.92)))',1000)
);

```

The ST_MPolyFromWKB() function

The **ST_MPolyFromWKB()** function takes a well-known binary representation of type ST_MultiPolygon and a spatial reference ID to return an ST_MultiPolygon.

Syntax

```
ST_MPolyFromWKB (WKB lvarchar, SRID integer)
```

Return type

ST_MultiPolygon

Example

The **lots** table stores the **lot_id**, which uniquely identifies each lot, and the lot multipolygon that contains the lot line geometry:

```

CREATE TABLE lots (lot_id integer,
                    lot      ST_MultiPolygon);

```

This code fragment populates the **lots** table:

```

/* Create the SQL insert statement to populate the lots table.
 * The question marks are parameter markers that indicate the
 * column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO lots (lot_id, lot) "
        "VALUES(?, ST_MpolyFromWKB(?, %d)", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry to the second parameter. */
pcbvalue2 = lot_wkb_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_wkb_len, 0,
                      lot_wkb_buf, lot_wkb_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The SE_Nearest() and SE_NearestBbox() functions

The **SE_Nearest()** function allows you to query for the nearest-neighbors to a specified geometry. The **SE_Nearest()** function uses an R-tree index, which you must create if it does not already exist. Query results are returned in order of increasing distance from the query object. The distance is measured using the same algorithm as used by the **ST_Distance()** function.

The **SE_NearestBBox()** function is similar to **SE_Nearest()**, but distances are measured between objects' bounding boxes (envelopes). Because this is a simpler calculation, **SE_NearestBBox()** executes more quickly, but may return objects in a different order, depending on the actual shape of the objects.

These functions can only be used in the WHERE clause of a query.

Important: To use the **SE_Nearest()** and **SE_NearestBBox()** functions, you must be using IBM Informix, Version 9.3 or later.

Required: You must create an R-tree index on the geometry column on which you want to perform nearest-neighbor queries.

Syntax

```
SE_Nearest (g1 ST_Geometry, g2 ST_Geometry)
```

```
SE_NearestBbox (g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The **cities** table contains the names and locations of world cities:

```
CREATE TABLE cities (name varchar(255),
                    locn ST_Point);
```

Populate this table with data from a DB-Access load file, **cities.load**, (this data file is included with the IBM Informix Spatial DataBlade Module as part of this example; it contains the names and locations of approximately 300 world cities), as the example shows:

```
LOAD FROM cities.load INSERT INTO cities;
```

Create an R-tree index on the **locn** column (this is required by the **SE_Nearest()** function:

```
CREATE INDEX cities_idx ON cities (locn ST_Geometry_ops) USING RTREE;
```

```
UPDATE STATISTICS FOR TABLE cities (locn);
```

Now search for the five cities nearest London:

```
SELECT FIRST 5 name FROM cities
  WHERE SE_Nearest(locn, '0 point(0 51)');
```

```
name London
```

```
name Birmingham
```

```
name Paris
```

```
name Nantes
```

```
name Amsterdam
```

Warning: Using a fragmented R-tree index for nearest-neighbor queries raises an error. Results will not be returned in nearest distance order because the query is executed on each separate index fragment, and results from each fragment are combined in an unspecified order.

The ST_NumGeometries() function

The **ST_NumGeometries()** function takes a ST_GeomCollection (ST_MultiPoint, ST_MultiLineString, or ST_MultiPolygon) and returns the number of geometries in the collection.

Syntax

```
ST_NumGeometries(mpt1 ST_MultiPoint)
ST_NumGeometries(mln1 ST_MultiLineString)
ST_NumGeometries(mp11 ST_MultiPolygon)
```

Return type

INTEGER

Example

The city engineer needs to know the number of distinct buildings associated with each building footprint.

The building footprints are stored in the **buildingfootprints** table that was created with the following CREATE TABLE statement:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);
```

The query lists the **building_id** that uniquely identifies each building and the number of buildings in each footprint with the **ST_NumGeometries()** function:

```
SELECT building_id, ST_NumGeometries(footprint) no_of_buildings
FROM buildingfootprints;
```

```
building_id no_of_buildings
          506                1
          543                1
          1208               1
          178                1
```

The ST_NumInteriorRing() function

The **ST_NumInteriorRing()** function takes an ST_Polygon and returns the number of its interior rings.

Syntax

```
ST_NumInteriorRing(p11 ST_Polygon)
```

Return type

INTEGER

Example

An ornithologist studying a bird population on several South Sea islands wants to identify which islands contain one or more lakes, because the bird species of interest feeds only in freshwater lakes.

The **ID** and **name** columns of the **islands** table identifies each island, while the **land** ST_Polygon column stores the island geometry:

```
CREATE TABLE islands (id    integer,
                       name  varchar(32),
                       land  ST_Polygon);
```

Because interior rings represent the lakes, the **ST_NumInteriorRing()** function lists only those islands that have at least one interior ring:

```
SELECT name
FROM islands
WHERE ST_NumInteriorRing(land) > 0;
```

The ST_NumPoints() function

The **ST_NumPoints()** function returns the number of points in an ST_Geometry.

Syntax

```
ST_NumPoints(g1 ST_Geometry)
```

Return type

INTEGER

Example

The **numpoints_test** table has two columns: **geotype**, a VARCHAR column that contains a description of the type of geometry; and **g1**, an ST_Geometry type that contains the geometry itself:

```
CREATE TABLE numpoints_test (geotype varchar(12),
                              g1      ST_Geometry);
```

The following INSERT statements insert a point, a linestring, and a polygon:

```
INSERT INTO numpoints_test VALUES(
    'point',
    ST_PointFromText('point (10.02 20.01)',1000)
);

INSERT INTO numpoints_test VALUES(
    'linestring',
    ST_LineFromText('linestring (10.02 20.01, 23.73 21.92)',1000)
);

INSERT INTO numpoints_test VALUES(
    'polygon',
    ST_PolyFromText('polygon ((10.02 20.01, 23.73 21.92, 24.51
12.98, 11.64 13.42, 10.02 20.01))',1000)
);
```

The query lists the geometry type and the number of points in each:

```
SELECT geotype, ST_NumPoints(g1) Number_of_points
FROM numpoints_test;

geotype      number_of_points
```

point	1
linestring	2
polygon	5

The SE_OutOfRowSize() function

The **SE_OutOfRowSize()** function returns the size of the out-of-row portion of a geometry. Geometries which are larger than 930 bytes (for example, polygons with many vertices) have an in-row component and an out-of-row component; the out-of-row component is stored in an sbspace.

If a geometry has no out-of-row component, **SE_OutOfRowSize()** returns 0.

You can use this function to obtain an estimate of the amount of disk space consumed by one or more geometries. However, this function does not account for dbspace and sbspace overhead, so cannot be used to obtain an exact total.

Syntax

```
SE_OutOfRowSize(ST_Geometry)
```

Return type

INTEGER

See also

“The SE_InRowSize() function” on page 8-52

“The SE_TotalSize() function” on page 8-107

The ST_Overlaps() function

The **ST_Overlaps()** function takes two ST_Geometry objects and returns t (TRUE) if the intersection of the objects results in an ST_Geometry object of the same dimension but not equal to either source object; otherwise, it returns f (FALSE).

Syntax

```
ST_Overlaps(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The county supervisor needs a list of hazardous waste sites whose five-mile radius overlaps sensitive areas.

The **sensitive_areas** table contains several columns that describe the threatened institutions in addition to the **zone** column, which stores the institution ST_Polygon geometries:

```
CREATE TABLE sensitive_areas (id      integer,
                             name    varchar(128),
                             size    float,
                             type    varchar(10),
                             zone    ST_Polygon);
```

The **hazardous_sites** table stores the identity of the sites in the **site_id** and **name** columns, while the actual geographic location of each site is stored in the **location** point column:

```
CREATE TABLE hazardous_sites (site_id integer,
                               name varchar(40),
                               location ST_Point);
```

The **sensitive_areas** and **hazardous_sites** tables are joined by the **ST_Overlaps()** function, which returns t (TRUE) for all **sensitive_areas** rows whose **zone** polygons overlap the buffered five-mile radius of the **hazardous_sites** location points:

```
SELECT hs.name hazardous_site, sa.name sensitive_area
FROM hazardous_sites hs, sensitive_areas sa
WHERE ST_Overlaps(ST_Buffer(hs.location,(26400)),sa.zone);
```

```
hazardous_site Landmark Industrial
sensitive_area Johnson County Hospital

hazardous_site Landmark Industrial
sensitive_area Summerhill Elementary School
```

The following figure shows that the hospital and the school overlap the five-mile radius of the county's two hazardous waste sites, while the nursing home does not.

Figure 8-10. Using the **ST_Overlaps()** function

The **SE_ParamGet()** function

The **SE_ParamGet()** function with no arguments returns the values of all parameters. Calling **SE_ParamGet()** with a parameter name in quotation marks returns the current value of the named parameter.

Syntax

SE_ParamSet(name lvarchar) returns lvarchar
SE_ParamSet() returns lvarchar

Return type

LVARCHAR

Example

```
execute function SE_ParamGet();  
execute function SE_ParamGet('MemMode');
```

Related reference:

“Optimize spatial queries” on page 1-12

The SE_ParamSet() function

The **SE_ParamSet()** function with no arguments returns usage information. Calling **SE_ParamSet()** with a parameter name in quotation marks and a value sets the parameter to the specified value. The new value is returned. Parameter names are not case-sensitive. Quotation marks are not required for numeric values.

Syntax

SE_ParamSet(name lvarchar, value lvarchar) returns lvarchar
SE_ParamSet() returns lvarchar

Return type

LVARCHAR

Example

```
execute function SE_ParamSet();  
execute function SE_ParamSet('memmode', '0');  
execute function SE_ParamSet('MemMode', 1);
```

Related reference:

“Optimize spatial queries” on page 1-12

The ST_Perimeter() function

The **ST_Perimeter()** function returns the perimeter of a polygon or multipolygon.

Syntax

ST_Perimeter(s ST_Polygon)
ST_Perimeter(ms ST_MultiPolygon)

Return type

DOUBLE PRECISION

Example

An ecologist studying shoreline birds needs to determine the shoreline for the lakes within a particular area. The lakes are stored as **ST_MultiPolygon** type in the **waterbodies** table, created with the following **CREATE TABLE** statement:

```
CREATE TABLE WATERBODIES (wbid integer, waterbody ST_MultiPolygon);
```

In the following SELECT statement, the **ST_Perimeter()** function returns the perimeter surrounding each body of water, while the SUM operator aggregates the perimeters to return their total:

```
SELECT SUM(ST_Perimeter(waterbody)) FROM waterbodies;
```

The SE_PerpendicularPoint() function

The **SE_PerpendicularPoint()** function finds the perpendicular projection of a point on to the nearest segment of a linestring or multilinestring. If two or more such perpendicular projected points are equidistant from the input point, they are all returned. If no perpendicular point can be constructed, an empty point is returned.

If the input linestring has Z values or measures, the Z value or measure of the perpendicular point are computed by linear interpolation between the adjacent vertices.

Syntax

```
SE_PerpendicularPoint(ST_LineString, ST_Point)
```

```
SE_PerpendicularPoint(ST_MultiLineString, ST_Point)
```

Return type

ST_MultiPoint

Example

```
CREATE TABLE linestring_test (line ST_LineString);
```

```
-- Create a U-shaped linestring:
INSERT INTO linestring_test VALUES (
  ST_LineFromText('linestring z (0 10 1, 0 0 3, 10 0 5, 10 10 7)', 0)
);
```

```
-- Perpendicular point is coincident with the input point,
-- on the base of the U:
SELECT SE_PerpendicularPoint(line, ST_PointFromText('point(5 0)', 0))
  FROM linestring_test;
```

```
(expression)  0 MULTIPOINT Z (5 0 4)
```

```
-- Perpendicular points are located on all three segments of the U:
SELECT SE_PerpendicularPoint(line, ST_PointFromText('point(5 5)', 0))
  FROM linestring_test;
```

```
(expression)  0 MULTIPOINT Z (0 5 2, 5 0 4, 10 5 6)
```

```
-- Perpendicular points are located at the endpoints of the U:
SELECT SE_PerpendicularPoint(line, ST_PointFromText('point(5 10)', 0))
  FROM linestring_test;
```

```
(expression)  0 MULTIPOINT Z (0 10 1, 10 10 7)
```

```
-- Perpendicular point is on the base of the U:
SELECT SE_PerpendicularPoint(line, ST_PointFromText('point(5 15)', 0))
  FROM linestring_test;
```

```
(expression)  0 MULTIPOINT Z (5 0 4)
```

```
-- No perpendicular point can be constructed:
SELECT SE_PerpendicularPoint(line, ST_PointFromText('point(15 15)', 0))
      FROM linestring_test;

(expression) 0 POINT EMPTY
```

The ST_Point() function

The **ST_Point()** function returns an ST_Point, given an X-coordinate, Y-coordinate, and spatial reference ID.

Syntax

```
ST_Point(X double precision, Y double precision, SRID integer)
```

Return type

ST_Point

Example

The following CREATE TABLE statement creates the **point_test** table, which has a single point column, **pt1**:

```
CREATE TABLE point_test (pt1 ST_Point);
```

The **ST_Point()** function converts the point coordinates into an ST_Point geometry before the INSERT statement inserts it into the **pt1** column:

```
INSERT INTO point_test VALUES(
  ST_Point(10.01,20.03,1000)
);
```

The ST_PointAtDistance() function

The **ST_PointAtDistance()** function returns the point the specified distance from the start of the line. Z coordinates and measures are ignored.

Syntax

```
ST_PointAtDistance (ST_LineString, float)
ST_PointAtDistance (ST_MultiLineString, float)
```

Return type

ST_Point

Example

The following SQL statement creates the **sample_geometries** table with two columns. The ID column uniquely identifies each row. The **geometry** ST_LineString column stores sample geometries.

```
CREATE TABLE sample_geometries(id INTEGER, geometry ST_LINestring);
```

The following SQL statement inserts two rows into the **sample_geometries** table:

```
INSERT INTO sample_geometries(id, geometry)
VALUES
(1,ST_LineString('LINESTRING ZM(0 0 0 0, 10 100 1000 10000)',1)),
(2,ST_LineString('LINESTRING ZM(10 100 1000 10000, 0 0 0 0)',1));
```

The following SELECT statement and the corresponding result set show how to use the **ST_PointAtDistance()** function to find points at a distance of 15 coordinate units from the start of the linestring.

```
SELECT ID, VARCHAR(ST_AsText(ST_PointAtDistance(geometry, 15)), 50) AS POINTAT
FROM sample_geometries;
```

```
ID          POINTAT
-----
1 POINT ZM(1.492556 14.925558 149 1493)
2 POINT ZM(8.507444 85.074442 851 8507)
```

2 record(s) selected.

The **ST_PointFromGML()** function

The **ST_PointFromGML()** function takes a GML2 or GML3 string representation of an **ST_Point** and an optional spatial reference ID and returns a point object.

Syntax

```
ST_PointFromGML(gmlstring lvarchar)
ST_PointFromGML(gmlstring lvarchar, SRID integer)
```

Return type

ST_Point

Example

The **point_t** table contains the **gid** INTEGER column, which uniquely identifies each row, the **pdesc** column which describes the point, and the **p1** column which stores the point. In this example, GML3 is shown.

```
CREATE TABLE point_t (gid INTEGER, pdesc VARCHAR(30), p1 ST_Point);
```

```
INSERT INTO point_t VALUES(
1,
'This point is a simple XY point',
ST_PointFromGML('<gml:Point srsName="DEFAULT" srsDimension="2">
<gml:pos>10.02 20.01</gml:pos></gml:Point>',1000)) ;
```

```
INSERT INTO point_t VALUES(
2,
'This point is a XYZ point',
ST_PointFromGML('<gml:Point srsName="DEFAULT" srsDimension="3">
<gml:pos>10.02 20.01 5</gml:pos></gml:Point>',1000)) ;
```

```
INSERT INTO point_t VALUES(
3,
'This point is a XYM point',
ST_PointFromGML('<gml:Point srsName="DEFAULT" srsDimension="3">
<gml:pos>10.02 20.01 7</gml:pos></gml:Point>',1000));
```

```
INSERT INTO point_t VALUES(
4,
'This point is a XYZM point',
ST_PointFromGML('<gml:Point srsName="DEFAULT" srsDimension="4">
<gml:pos>10.02 20.01 5 7</gml:pos></gml:Point>',1000)) ;
```

```
INSERT INTO point_t VALUES(
5,
'This point is an empty point',
ST_PointFromGML('<gml:Point xsi:nil="true" srsName="UNKNOWN:0"
srsDimension="2"/>',1000));
```

The ST_PointFromKML() function

The **ST_PointFromKML()** function takes a KML Point string and an optional spatial reference ID and returns a point object. A Point string can contain the elements of <coordinates>, <extrude>, <tessellate>, and <altitudeMode>.

Syntax

```
ST_PointFromKML(kmlstring lvarchar)
ST_PointFromKML(kmlstring lvarchar, SRID integer)
```

Return type

ST_Point

Example

```
EXECUTE FUNCTION ST_PointFromKML('<Point><coordinates>-122.44255879,37.80666418
</coordinates></Point>',3);
```

Output:

```
3 POINT (-122.44255879 37.80666418)
```

The SE_PointFromShape() function

The **SE_PointFromShape()** function creates an ST_Point from a shape of type point and a spatial reference ID.

Syntax

```
SE_PointFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_Point

Example

The hazardous sites are stored in the **hazardous_sites** table created with the CREATE TABLE statement that follows. The **location** column, defined as a point, stores a location that is the geographic center of each hazardous site:

```
CREATE TABLE hazardous_sites (site_id integer,
                                name      varchar(40),
                                location  ST_Point);
```

The program fragment populates the **hazardous_sites** table:

```
/* Create the SQL insert statement to populate the hazardous_sites
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO hazardous_sites (site_id, name, location) "
        "VALUES(?, ?, SE_PointFromShape(?, %d)", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the site_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                        SQL_INTEGER, 0, 0,
                        &site_id, 0, &pcbvalue1);
```

```

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, 0, 0,
                      name, 0, &pcbvalue2);

/* Bind the location geometry to the third parameter. */
pcbvalue3 = location_shape_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, location_shape_len, 0,
                      location_shape_buf, location_shape_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The ST_PointFromText() function

The **ST_PointFromText()** function takes a well-known text representation of type point and a spatial reference ID and returns a point.

Syntax

```
ST_PointFromText(WKT lvarchar, SRID integer)
```

Return type

ST_Point

Example

The **point_test** table is created with the single ST_Point column **pt1**:

```
CREATE TABLE multipoint_test (gid smallint,
                             mpt1 ST_MultiPoint);
```

The **ST_PointFromText()** function converts the point text coordinates to the ST_Point format before the INSERT statement inserts the point into the **pt1** column:

```
INSERT INTO multipoint_test VALUES(
    1,
    ST_MPointFromText('multipoint(10.01 20.03,10.52 40.11,30.29
41.56,31.78 10.74)',1000)
);
```

The ST_PointFromWKB() function

The **ST_PointFromWKB()** function takes a well-known binary representation of type ST_Point and a spatial reference ID to return an ST_Point.

Syntax

```
ST_PointFromWKB (WKB lvarchar, SRID integer)
```

Return type

ST_Point

Example

The hazardous sites are stored in the **hazardous_sites** table created with the CREATE TABLE statement that follows. The **location** column, defined as an ST_Point, stores a location that is the geographic center of each hazardous site:

```
CREATE TABLE hazardous_sites (site_id integer,
                               name      varchar(40),
                               location  ST_Point);
```

The program fragment populates the **hazardous_sites** table:

```
/* Create the SQL insert statement to populate the hazardous_sites
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO hazardous_sites (site_id, name, location) "
        "VALUES(?, ?, ST_PointFromWKB(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the site_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &site_id, 0, &pcbvalue1);

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, 0, 0,
                      name, 0, &pcbvalue2);

/* Bind the location geometry to the third parameter. */
pcbvalue3 = location_wkb_len;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, location_wkb_len, 0,
                      location_wkb_buf, location_wkb_len, &pcbvalue3);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_PointN() function

The **ST_PointN()** function takes an ST_LineString and an INTEGER index and returns a point that is the *n*th vertex in the ST_LineString's path. (The numbering of the vertices in the linestring starts with 1.)

Syntax

```
ST_PointN (ln1 ST_LineString, index integer)
```

Return type

ST_Point

Example

The **pointn_test** table is created with the **gid** column, which uniquely identifies each row, and the **ln1** ST_LineString column:

```
CREATE TABLE pointn_test (gid integer,
                          ln1 ST_LineString);
```

The following INSERT statements insert two linestring values. The first linestring does not have Z coordinates or measures, while the second linestring has both:

```
INSERT INTO pointn_test VALUES(
  1,
  ST_LineFromText('linestring (10.02 20.01,23.73 21.92,30.10 40.23)',1000)
);

INSERT INTO pointn_test VALUES(
  2,
  ST_LineFromText('linestring zm (10.02 20.01 5.0 7.0,23.73 21.92
6.5 7.1,30.10 40.23 6.9 7.2)',1000)
);
```

The query lists the **gid** column and the second vertex of each linestring. The first row results in an ST_Point without a Z coordinate or measure, while the second row results in an ST_Point with a Z coordinate and a measure. The **ST_PointN()** function will also include a Z coordinate or measure value if they exist in the source linestring:

```
SELECT gid, ST_PointN(1n1,2) the_2nd_vertex
FROM pointn_test;
```

```
gid          1
the_2nd_vertex 1000 POINT (23.73 21.92)

gid          2
the_2nd_vertex 1000 POINT ZM (23.73 21.92 6.5 7.1)
```

The ST_PointOnSurface() function

The **ST_PointOnSurface()** function takes an ST_Polygon or ST_MultiPolygon and returns an ST_Point guaranteed to lie on its surface.

Syntax

```
ST_PointOnSurface (p11 ST_Polygon)
ST_PointOnSurface (mp11 ST_MultiPolygon)
```

Return type

ST_Point

Example

The city engineer wants to create a label point for each building footprint.

The **buildingfootprints** table that was created with the following CREATE TABLE statement stores the building footprints:

```
CREATE TABLE buildingfootprints (building_id integer,
                                lot_id integer,
                                footprint ST_MultiPolygon);
```

The **ST_PointOnSurface()** function generates a point that is guaranteed to be on the surface of the building footprints:

```
SELECT building_id, ST_PointOnSurface(footprint)
FROM buildingfootprints;
```

```
building_id 506
(expression) 1000 POINT (12.5 49.5)
```

```

building_id 543
(expression) 1000 POINT (32 52.5)

building_id 1208
(expression) 1000 POINT (12.5 27.5)

building_id 178
(expression) 1000 POINT (32 30)

```

The ST_PolyFromGML() function

The **ST_PolyFromGML()** function takes a GML2 or GML3 string representation of an ST_Polygon and an optional spatial reference ID and returns a polygon object.

Syntax

```

ST_PolyFromGML(gmlstring lvarchar)
ST_PolyFromGML(gmlstring lvarchar, SRID integer)

```

Return type

ST_Polygon

Example

The **test_poly** table is created with the INTEGER column **id** and the ST_Polygon column **geom**:

```

CREATE TABLE test_poly(id INTEGER, geom ST_Polygon);

INSERT INTO test_poly VALUES(1,ST_PolyFromGML('<gml:Polygon
srsName="EPSG:4326" srsDimension="2">
<gml:exterior><gml:LinearRing><gml:posList dimension="2">
-84.36 32.49 -82.66 32.69 -82.15 32.46 -83.09 33.08 -83.37
33.19 -84.36 32.49</gml:posList></gml:LinearRing>
</gml:exterior>< /gml:Polygon',4));

```

This record specifies a spatial reference id of 4 (WGS84) and represents a two-dimensional six-sided polygon.

Output:

```

SELECT * FROM test_poly;

id      1
geom    4 POLYGON ((-84.3600000805 32.4900000536, -82.6599999799
                 32.6899999866, -82.1500000335 32.4600000469,
                 -83.0900000201 33.0800000738, -83.3700000268
                 33.1899999866, -84.3600000805 32.4900000536))

```

The ST_PolyFromKML() function

The **ST_PolyFromKML()** function takes a KML Polygon string representation and an optional spatial reference ID and returns a polygon object.

Syntax

```

ST_PolyFromKML(kmlstring lvarchar)
ST_PolyFromKML(kmlstring lvarchar, SRID integer)

```

Return type

ST_Polygon

Example

```
EXECUTE FUNCTION ST_PolyFromKML ('<Polygon><outerBoundaryIs>
<LinearRing>
<coordinates>-122.365662,37.826988,0
-122.365202,37.826302,0 -122.364581,37.82655,0
-122.365038,37.827237,0 -122.365662,37.826988,0
</coordinates></LinearRing></outerBoundaryIs>
</Polygon>',4);
```

Output:

```
4 POLYGON Z ((-122.365662056 37.8269879529 0, -122.365202058
37.8263019779 0, -122.364580958 37.8265500822 0,
-122.36503794 37.827237063 0, -122.365662056
37.8269879529 0))
```

The SE_PolyFromShape() function

The **SE_PolyFromShape()** function returns an ST_Polygon from a shape of type polygon and a spatial reference ID.

Syntax

```
SE_PolyFromShape(s1 lvarchar, SRID integer)
```

Return type

ST_Polygon

Example

The **sensitive_areas** table contains several columns that describe the threatened institutions in addition to the **zone** column, which stores the institution polygon geometries:

```
CREATE TABLE sensitive_areas (id      integer,
                               name    varchar(128),
                               size    float,
                               type    varchar(10),
                               zone    ST_Polygon);
```

The program fragment populates the **sensitive_areas** table. The question marks represent parameter markers for the **ID**, **name**, **size**, **type**, and **zone** values that will be retrieved at run time:

```
/* Create the SQL insert statement to populate the sensitive_areas
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO sensitive_areas (id, name, size, type, zone) "
        "VALUES(?, ?, ?, ?, SE_PolyFromShape(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &id, 0, &pcbvalue1);
```

```

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                        SQL_CHAR, 0, 0,
                        name, 0, &pcbvalue2);

/* Bind the size to the third parameter. */
pcbvalue3 = 0;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_FLOAT,
                        SQL_REAL, 0, 0,
                        &size, 0, &pcbvalue3);

/* Bind the type to the fourth parameter. */
pcbvalue4 = type_len;
rc = SQLBindParameter (hstmt, 4, SQL_PARAM_INPUT, SQL_C_CHAR,
                        SQL_VARCHAR, type_len, 0,
                        type, type_len, &pcbvalue4);

/* Bind the zone geometry to the fifth parameter. */
pcbvalue5 = zone_shape_len;
rc = SQLBindParameter (hstmt, 5, SQL_PARAM_INPUT, SQL_C_BINARY,
                        SQL_INFX_UDT_LVARCHAR, zone_shape_len, 0,
                        zone_shape_buf, zone_shape_len, &pcbvalue5);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The ST_PolyFromText() function

The **ST_PolyFromText()** function takes a well-known text representation of type ST_Polygon and a spatial reference ID and returns an ST_Polygon.

Syntax

```
ST_PolyFromText(wkt lvarchar, SRID integer)
```

Return type

ST_Polygon

Example

The **polygon_test** table is created with the single polygon column:

```
CREATE TABLE polygon_test (p11 ST_Polygon);
```

The following INSERT statement inserts a polygon into the **p11** polygon column using the **ST_PolyFromText()** function:

```
INSERT INTO polygon_test VALUES(
    ST_PolyFromText('polygon((10.01 20.03,10.52 40.11,30.29
41.56,31.78 10.74,10.01 20.03))',1000)
);
```

The ST_PolyFromWKB() function

The **ST_PolyFromWKB()** function takes a well-known binary representation of type ST_Polygon and a spatial reference ID to return an ST_Polygon.

Syntax

```
ST_PolyFromWKB(wkb lvarchar, SRID integer)
```

Return type

ST_Polygon

Example

The **sensitive_areas** table contains several columns that describe the threatened institutions in addition to the **zone** column, which stores the institution ST_Polygon geometries:

```
CREATE TABLE sensitive_areas (id      integer,
                              name    varchar(128),
                              size    float,
                              type    varchar(10),
                              zone    ST_Polygon);
```

The program fragment populates the **sensitive_areas** table:

```
/* Create the SQL insert statement to populate the sensitive_areas
 * table. The question marks are parameter markers that indicate
 * the column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO sensitive_areas (id, name, size, type, zone) "
        "VALUES(?, ?, ?, ?, ST_PolyFromWKB(?, %d))", srid);

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &id, 0, &pcbvalue1);

/* Bind the name to the second parameter. */
pcbvalue2 = name_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_CHAR, 0, 0,
                      name, 0, &pcbvalue2);

/* Bind the size to the third parameter. */
pcbvalue3 = 0;
rc = SQLBindParameter (hstmt, 3, SQL_PARAM_INPUT, SQL_C_FLOAT,
                      SQL_REAL, 0, 0,
                      &size, 0, &pcbvalue3);

/* Bind the type to the fourth parameter. */
pcbvalue4 = type_len;
rc = SQLBindParameter (hstmt, 4, SQL_PARAM_INPUT, SQL_C_CHAR,
                      SQL_VARCHAR, type_len, 0,
                      type, type_len, &pcbvalue4);

/* Bind the zone geometry to the fifth parameter. */
pcbvalue5 = zone_wkb_len;
rc = SQLBindParameter (hstmt, 5, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, zone_wkb_len, 0,
                      zone_wkb_buf, zone_wkb_len, &pcbvalue5);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);
```

The ST_Polygon() function

The **ST_Polygon()** function generates an ST_Polygon from a ring (an ST_LineString that is both simple and closed).

Syntax

ST_Polygon (In ST_LineString)

Return type

ST_Polygon

Example

The following CREATE TABLE statement creates the **polygon_test** table, which has a single column, **p1**:

```
CREATE TABLE polygon_test (p1 ST_polygon);
```

The INSERT statement converts a ring (an ST_LineString that is both closed and simple) into an ST_Polygon and inserts it into the **p1** column using the **ST_LineFromText()** function within the **ST_Polygon()** function:

```
INSERT INTO polygon_test VALUES(  
  ST_Polygon(ST_LineFromText('linestring (10.01 20.03, 20.94  
21.34, 35.93 10.04, 10.01 20.03)',1000))  
);
```

The ST_Relate() function

The **ST_Relate()** function compares two geometries and returns 1 (TRUE) if the geometries meet the conditions specified by the DE-9IM pattern matrix string; otherwise, 0 (FALSE) is returned.

Syntax

ST_Relate(g1 ST_Geometry, g2 ST_Geometry, patternMatrix lvarchar)

Return type

BOOLEAN

Example

A DE-9IM pattern matrix is a device for comparing geometries. There are several types of such matrices. For example, the *equals* pattern matrix will tell you if any two geometries are equal.

In this example, an equals pattern matrix, shown below, is read left to right, and top to bottom into the string ("T*F**FFF*"):

		b		
		Interior	Boundary	Exterior
a	Interior	T	*	F
	Boundary	*	*	F
	Exterior	F	F	*

Next, the table **relate_test** is created with the following CREATE TABLE statement:

```
CREATE TABLE relate_test (g1 ST_Geometry,  
  g2 ST_Geometry,  
  g3 ST_Geometry);
```

The following INSERT statements insert a sample subclass into the **relate_test** table:

```
INSERT INTO relate_test VALUES(
    ST_PointFromText('point (10.02 20.01)',1000),
    ST_PointFromText('point (10.02 20.01)',1000),
    ST_PointFromText('point (30.01 20.01)',1000)
);
```

The following SELECT statement and the corresponding result set lists the subclass name stored in the **geotype** column with the dimension of that geotype:

```
SELECT ST_Relate(g1,g2,"T*F**FFF*") equals,
       ST_Relate(g1,g3,"T*F**FFF*") not_equals
FROM relate_test;
```

```
equals not_equals
      t         f
```

The SE_Release() function

The **SE_Release()** function returns a text string containing the installed version and release date of the IBM Informix spatial extension.

Syntax

```
SE_Release()
```

Return type

A text string containing the installed version and release date.

The SE_ShapeToSQL() function

The **SE_ShapeToSQL()** function constructs an ST_Geometry given its ESRI shape representation. The SRID of the St_Geometry is 0.

Syntax

```
SE_ShapeToSQL(ShapeGeometry lvarchar)
```

Return type

```
ST_Geometry
```

Example

The following C code fragment contains ODBC functions that insert data into the **lots** table. The **lots** table was created with two columns: **lot_id**, which uniquely identifies each lot, and the **lot** polygon column, which contains the geometry of each lot:

```
CREATE TABLE lots (lot_id integer,
                  lot      ST_MultiPolygon);
```

The **SE_ShapeToSQL()** function converts shapes into ST_Geometry values. The INSERT statement contains parameter markers to accept the **lot_id** and the lot data, dynamically:

```
/* Create the SQL insert statement to populate the lots table.
 * The question marks are parameter markers that indicate the
 * column values that will be inserted at run time. */
```

```

sprintf(sql_stmt,
        "INSERT INTO lots (lot_id, lot) "
        "VALUES(?, SE_ShapeToSQL(?))");

/* Prepare the SQL statement for execution. */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry the second parameter. */
pcbvalue2 = lot_shape_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_shape_len, 0,
                      lot_shape_buf, lot_shape_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The SE_SpatialKey() function

The **SE_SpatialKey()** function generates a *sort key* for an ST_Geometry. A sort key is a numeric value that can be used to sort spatial objects according to their proximity to one another.

The sort key is computed by applying the Hilbert space-filling curve algorithm to the center point of an object's bounding box.

Syntax

```
SE_SpatialKey(g1 ST_Geometry)
```

Return type

A numeric sort key, as an INT8

Example

Create and populate a **cities** table containing the names and locations of world cities:

```
CREATE TABLE cities (name varchar(255),
                    locn ST_Point);
```

```
LOAD FROM cities.load INSERT INTO cities;
```

Create a clustered functional B-tree index. This rearranges the table data, placing it in spatial key sort order. Chapter 4, "R-tree indexes," on page 4-1, provides information about using indexes, in particular, R-tree indexes. For example:

```
CREATE CLUSTER INDEX cbt_idx ON cities (SE_SpatialKey(locn));
```

Create an R-tree index with the NO_SORT option:

```
CREATE INDEX locn_idx ON cities (locn ST_Geometry_ops)
  USING RTREE (BOTTOM_UP_BUILD='yes', NO_SORT='yes');
```

Drop the B-tree index; it is no longer needed:

```
DROP INDEX cbt_idx;
```

Related concepts:

“Bottom-up versus top-down index builds” on page 4-3

Related reference:

“Syntax for creating an R-tree index” on page 4-1

The ST_SRID() function

The **ST_SRID()** function takes an ST_Geometry object and returns its spatial reference ID.

Syntax

```
ST_SRID(g1 ST_Geometry)
```

Return type

INTEGER

Example

During the installation of the IBM Informix Spatial DataBlade Module, the **spatial_references** table is created by this CREATE TABLE statement:

```
CREATE TABLE sde.spatial_references
(
  srid          integer      NOT NULL,
  description   varchar(64),
  auth_name     varchar(255),
  auth_srid     integer,
  falsex       float        NOT NULL,
  falsey       float        NOT NULL,
  xyunits      float        NOT NULL,
  falsez       float        NOT NULL,
  zunits       float        NOT NULL,
  falsem       float        NOT NULL,
  munits       float        NOT NULL,
  srtext       char(2048)   NOT NULL,
  PRIMARY KEY (srid)
  CONSTRAINT sde.sp_ref_pk
);
```

Before you can create geometry and insert it into a table, you must enter the SRID of that geometry into the **spatial_references** table. This is a sample insert of a spatial reference system. The spatial reference system has an SRID value of 1, a false X, Y of (0,0), and its system units are 100. The Z coordinate and measure offsets are 0, while the Z coordinate and measure units are 1.

```
INSERT INTO spatial_references
  (srid, description, auth_name, auth_srid, falsex, falsey,
   xyunits, falsez, zunits, falsem, munits, srtext)
VALUES (1, NULL, NULL, NULL, 0, 0, 100, 0, 1, 0, 1, 'UNKNOWN');
```

Important: Choose the parameters of a **spatial_references** table entry with care. See “The spatial_references table” on page 1-5, for more information.

The following table is created for this example:

```
CREATE TABLE srid_test(g1 ST_Geometry);
```

In the next statement, an ST_Point geometry located at coordinate (10.01,50.76) is inserted into the geometry column **g1**. When the ST_Point geometry is created by the **ST_PointFromText()** function, it is assigned the SRID value of 1:

```
INSERT INTO srid_test VALUES(
  ST_PointFromText('point(10.01 50.76)',1000)
);
```

The **ST_SRID()** function returns the spatial reference ID of the geometry just entered:

```
SELECT ST_SRID(g1)
  FROM srid_test;
```

```
(expression)
          1000
```

The SE_SRID_Authority() function

The **SE_SRID_Authority()** function takes a spatial reference ID and returns the Authority Name and Authority SRID as an LVARCHAR string in the form AuthName:SRID. If the AuthName is null in the sde.spatial_references table for a given spatial reference ID, the srtext is returned.

Syntax

```
SE_SRID_Authority(SRID integer)
```

Return type

LVARCHAR

Example

```
select SE_SRID_Authority(srid) from sde.spatial_references;
```

```
(expression) UNKNOWN:0
(expression) EPSG:4135
(expression) EPSG:4267
(expression) EPSG:4269
(expression) EPSG:4326
(expression) UNKNOWN:0
(expression) UNKNOWN:0
(expression) UNKNOWN:0
(expression) AUTH_NAME:1234
(expression) GEOGCS["GCS_01d_Hawaiian",
  DATUM["D_01dHawaiian",
  SPHEROID["Clarke_1866",6378206.4,294.9786982]],
  PRIMEM["Greenwich",0],UNIT["Degree",0.01745329 25199433]]
```

10 row(s) retrieved.

The ST_StartPoint() function

The **ST_StartPoint()** function returns the first point of a linestring.

Syntax

```
ST_StartPoint(ln1 ST_LineString)
```

Return type

ST_Point

Example

The **startpoint_test** table is created with the **gid** INTEGER column, which uniquely identifies the rows of the table, and the **ln1** ST_LineString column:

```
CREATE TABLE startpoint_test (gid integer,  
                               ln1 ST_LineString);
```

The following INSERT statements insert the ST_LineStrings into the **ln1** column. The first ST_LineString does not have Z coordinates or measures, while the second ST_LineString has both:

```
INSERT INTO startpoint_test VALUES(  
    1,  
    ST_LineFromText('linestring (10.02 20.01,23.73 21.92,30.10 40.23)', 1000)  
);
```

```
INSERT INTO startpoint_test VALUES(  
    2,  
    ST_LineFromText('linestring zm (10.02 20.01 5.0 7.0,23.73 21.92  
6.5 7.1,30.10 40.23 6.9 7.2)', 1000)  
);
```

The **ST_StartPoint()** function extracts the first point of each ST_LineString. The first point in the list does not have a Z coordinate or a measure, while the second point has both because the source linestring does:

```
SELECT gid, ST_StartPoint(ln1) Startpoint  
FROM startpoint_test;
```

```
gid          1  
startpoint  1000 POINT (10.02 20.01)
```

```
gid          2  
startpoint  1000 POINT ZM (10.02 20.01 5 7)
```

See also

“The ST_EndPoint() function” on page 8-36

The ST_SymDifference() function

The **ST_StartPoint()** function takes two ST_Geometry objects and returns a ST_Geometry object that is composed of the parts of the source objects that are not common to both.

Syntax

```
ST_SymDifference (g1 ST_Geometry, g2 ST_Geometry)
```

Return type

ST_Geometry

Example

For a special report, the county supervisor must determine the area of sensitive areas and five-mile hazardous site radii that do not intersect.

The **sensitive_areas** table contains several columns that describe the threatened institutions, in addition to the **zone** column, which stores the institutions' ST_Polygon geometries:

```
CREATE TABLE sensitive_areas (id      integer,
                              name    varchar(128),
                              size    float,
                              type    varchar(10),
                              zone    ST_Polygon);
```

The **hazardous_sites** table stores the identity of the sites in the **site_id** and **name** columns, while the actual geographic location of each site is stored in the **location** point column:

```
CREATE TABLE hazardous_sites (site_id integer,
                               name     varchar(40),
                               location ST_Point);
```

The **ST_Buffer()** function generates a five-mile buffer surrounding the hazardous waste site locations. The **ST_StartPoint()** function returns the polygons of the buffered hazardous waste site polygons and the sensitive areas that do not intersect:

```
SELECT sa.name sensitive_area, hs.name hazardous_site,
       ST_Area(ST_SymDifference(ST_Buffer(hs.location,(5 * 5280)),sa.zone)::
       ST_MultiPolygon) area
FROM hazardous_sites hs, sensitive_areas sa;
```

The following figure shows that the symmetric difference of the hazardous waste sites and the sensitive areas results in the subtraction of the intersected areas.

Figure 8-11. Using the ST_SymDifference function

Related reference:

“The ST_SymDifference() function” on page 7-10

The SE_TotalSize() function

The **SE_TotalSize()** function returns the sum of the in-row and out-of-row components of a geometry.

You can use this function to obtain an estimate of the amount of disk space consumed by one or more geometries. However, this function does not account for dbspace and sbospace overhead, so cannot be used to obtain an exact total.

Syntax

```
SE_TotalSize(ST_Geometry)
```

Return type

INTEGER

See also

“The SE_InRowSize() function” on page 8-52

“The SE_OutOfRowSize() function” on page 8-87

The ST_Touches() function

The **ST_Touches()** function returns t (TRUE) if none of the points common to both geometries intersect the interiors of both geometries; otherwise, it returns f (FALSE). At least one geometry must be an ST_LineString, ST_Polygon, ST_MultiLineString, or ST_MultiPolygon.

Syntax

```
ST_Touches(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

The GIS technician has been asked to provide a list of all sewer lines whose endpoints intersect another sewer line.

The **sewerlines** table is created with three columns. The first column, **sewer_id**, uniquely identifies each sewer line. The INTEGER **class** column identifies the type of sewer line, generally associated with the line's capacity. The **sewer** ST_LineString column stores the sewer line's geometry:

```
CREATE TABLE sewerlines (sewer_id integer,  
                        class integer,  
                        sewer ST_LineString);
```

The query returns a list of **sewer_ids** that touch one another:

```
SELECT s1.sewer_id, s2.sewer_id  
FROM sewerlines s1, sewerlines s2  
WHERE ST_Touches(s1.sewer, s2.sewer);
```

Related reference:

“The ST_Touches() function” on page 7-3

“The ST_Touches() function” on page 7-18

The SE_Trace() function

The **SE_Trace()** function provides tracing for spatial data type functions.

The **SE_Trace()** function provides the following levels of tracing:

Level 1

SQL function entry and exit

Level 2

Secondary function entry and exit

Level 3

Miscellaneous additional tracing

Important: You should turn off tracing during normal use, because it can generate tremendous amounts of trace output data. It is intended for use by IBM Software Support in isolating problems.

Syntax

```
SE_Trace(pathname lvarchar, level integer)
```

Where *pathname* is a file name and full path on the server machine and *level* is 1, 2 or 3.

Return type

The text string OK, if the function was successfully executed

Example

This example shows the file separator for UNIX: a forward slash (/). If you are using a Windows platform, substitute the UNIX file separator with a backslash (\) in the path name.

```
execute function SE_Trace ('/tmp/spatial.trc', 1);
```

The ST_Transform() function

The **ST_Transform()** function transforms an ST_Geometry into the specified spatial reference system.

The transformations allowed in the current version of the Spatial DataBlade are:

- Between two UNKNOWN coordinate systems (that is, the **srttext** column in the **spatial_references** table for both SRIDs contains UNKNOWN)
- Between a projected coordinate system and an unprojected coordinate system, in which the underlying geographic coordinate systems are the same
- Between two projected coordinate systems, in which the underlying geographic coordinate systems are the same
- Between two coordinate systems with the same geographic coordinate system (these are coordinate systems with a difference in false origin or system unit only)

Appendix B, “OGC well-known text representation of spatial reference systems,” on page B-1, contains information about supported coordinate systems and their constituent parts.

Syntax

```
ST_Transform(g ST_Geometry, SRID integer)
```

Return type

ST_Geometry

Examples

Example 1: Changing the false origin of a spatial reference system

Suppose you created a **spatial_references** table entry suitable for Australia. You can do this with the **SE_CreateSrid()** function as follows:

```
EXECUTE FUNCTION SE_CreateSrid (110, -45, 156, -10,  
                                "Australia: lat/lon coords");
```

(expression)

1002

Now load all of your data for Australia. In this example we just create a table with a few points.

```
CREATE TABLE aus_locns (name varchar(128), locn ST_Point);  
  
INSERT INTO aus_locns VALUES ("Adelaide", '1002 point(139.14 -34.87)');  
INSERT INTO aus_locns VALUES ("Brisbane", '1002 point(153.36 -27.86)');  
INSERT INTO aus_locns VALUES ("Canberra", '1002 point(148.84 -35.56)');  
INSERT INTO aus_locns VALUES ("Melbourne", '1002 point(145.01 -37.94)');  
INSERT INTO aus_locns VALUES ("Perth", '1002 point(116.04 -32.12)');  
INSERT INTO aus_locns VALUES ("Sydney", '1002 point(151.37 -33.77)');
```

After loading all of your data for the Australian mainland, you realize you need to include data for a few outlying islands, such as Norfolk Island and the Cocos Islands. However, the false origin and scale factor that you chose for SRID 1002 will not work for these islands as well:

```
INSERT INTO aus_locns VALUES ("Norfolk Is.", '1002 point(167.83 -29.24)');  
(USE19) - Coordinates out of bounds in ST_PointIn.
```

```
INSERT INTO aus_locns VALUES ("Cocos Is.", '1002 point( 96.52 -12.08)');  
(USE19) - Coordinates out of bounds in ST_PointIn.
```

The solution is to create a new **spatial_references** table entry with a false origin and scale factor that accommodates both the old data and new data, and then update the old data:

```
EXECUTE FUNCTION SE_CreateSrid (95, -55, 170, -10,  
                                "Australia + outer islands: lat/lon coords");
```

(expression)

1003

```
INSERT INTO aus_locns VALUES ("Norfolk Is.", '1003 point(167.83 -29.24)');  
INSERT INTO aus_locns VALUES ("Cocos Is.", '1003 point( 96.52 -12.08)');
```

```
UPDATE aus_locns  
SET locn = ST_Transform(locn, 1003)::ST_Point  
WHERE ST_Srid(locn) = 1002;
```

Example 2: Projecting data dynamically

In a typical application, spatial data is stored in unprojected latitude and longitude format. Then, when you draw a map, you retrieve the data in a particular projection, letting the IBM Informix Spatial DataBlade Module do the necessary transformations as it retrieves data from a table.

First, create a **spatial_references** table entry that is suitable for your unprojected data. For this example we use the 1983 North American datum. Because this is a well-known, standard datum we can use the **SE_CreateSrtxt()** function to create the **srtxt** field:

```

INSERT INTO spatial_references
  (srid, description, falsex, falsey, xyunits,
   falsez, zunits, falsem, munits, srtext)
VALUES (1004, "Unprojected lat/lon, NAD 83 datum",
       -180, -90, 5000000, 0, 1000, 0, 1000,
       SE_CreateSrtext(4269));

```

Now create a table and load your data:

```

CREATE TABLE airports (id char(4),
                       name varchar(128),
                       locn ST_Point);

INSERT INTO airports VALUES(
  'BTM', 'Bert Mooney',          '1004 point(-112.4975 45.9548)');
INSERT INTO airports VALUES(
  'BZN', 'Gallatin Field',      '1004 point(-111.1530 45.7769)');
INSERT INTO airports VALUES(
  'COD', 'Yellowstone Regional', '1004 point(-109.0238 44.5202)');
INSERT INTO airports VALUES(
  'JAC', 'Jackson Hole',        '1004 point(-110.7377 43.6073)');
INSERT INTO airports VALUES(
  'IDA', 'Fanning Field',       '1004 point(-112.0702 43.5146)');

```

Create one or more **spatial_references** table entries for any projections that you will need. Be sure that the underlying geographic coordinate system (in this case, NAD 83) is the same; this version of the IBM Informix Spatial DataBlade Module does not perform datum conversions:

```

INSERT INTO spatial_references
  (srid, description, falsex, falsey, xyunits,
   falsez, zunits, falsem, munits, srtext)
VALUES (1005, "UTM zone 12N, NAD 83 datum",
       336000, 4760000, 1000, 0, 1000, 0, 1000,
       SE_CreateSrtext(26912));

```

Transform the data to a projected coordinate system on an as needed basis:

```

SELECT id, ST_Transform(locn, 1005) as utm FROM airports;

```

```

id  BTM
utm 1005 POINT (383951.152 5090115.666)

```

```

id  BZN
utm 1005 POINT (488105.331 5069271.419)

```

```

id  COD
utm 1005 POINT (657049.762 4931552.365)

```

```

id  JAC
utm 1005 POINT (521167.881 4828291.447)

```

```

id  IDA
utm 1005 POINT (413500.979 4818519.081)

```

Related reference:

Appendix B, "OGC well-known text representation of spatial reference systems," on page B-1

The ST_Union() function

The **ST_Union()** function returns an ST_Geometry object that is the union of two source objects.

Syntax

```
ST_Union(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

ST_Geometry

Example

The **sensitive_areas** table contains several columns that describe the threatened institutions in addition to the **zone** column, which stores the institutions' ST_Polygon geometries:

```
CREATE TABLE sensitive_areas (id      integer,
                               name    varchar(128),
                               size    float,
                               type    varchar(10),
                               zone    ST_Polygon);
```

The **hazardous_sites** table stores the identity of the sites in the **site_id** and **name** columns, while the actual geographic location of each site is stored in the **location** point column:

```
CREATE TABLE hazardous_sites (site_id integer,
                               name     varchar(40),
                               location ST_Point);
```

The **ST_Buffer()** function generates a five-mile buffer surrounding the hazardous waste site locations. The **ST_Union()** function generates polygons from the union of the buffered hazardous waste site polygons and the sensitive areas. The **ST_Area()** function returns the unioned polygon area:

```
SELECT sa.name sensitive_area, hs.name hazardous_site,
       ST_Area(ST_Union(ST_Buffer(hs.location,(5 * 5280)),sa.zone)::
       ST_MultiPolygon) area
FROM hazardous_sites hs, sensitive_areas sa;
```

See also

"The SE_Dissolve() function" on page 8-34

Related reference:

"The ST_Union() function" on page 7-9

The SE_VertexAppend() function

The **SE_VertexAppend()** function appends a vertex to the end of an ST_LineString. If the linestring has Z values or measures, the vertex to be appended must also have Z values or measures.

Syntax

```
SE_VertexAppend (ST_LineString, ST_Point)
```

Return type

ST_LineString

The SE_VertexDelete() function

The **SE_VertexDelete()** function deletes a vertex from a geometry. You must supply the exact vertex to be deleted, including Z value and measure if applicable. All vertices in the geometry which match this value will be deleted.

Syntax

```
SE_VertexDelete (ST_Geometry, ST_Point)
```

Return type

ST_Geometry

The SE_VertexUpdate() function

The **SE_VertexUpdate()** function changes the value of a vertex in a geometry. You must supply both the exact old value and the new value of the vertex to be altered. If the input geometry has Z values or measures, you must supply them as well. All vertices in the geometry which match the old value will be updated.

Syntax

```
SE_VertexUpdate (ST_Geometry, old ST_Point, new ST_Point)
```

Return type

ST_Geometry

The ST_Within() function

The **ST_Within()** function returns t (TRUE) if the first object is completely within the second; otherwise, it returns f (FALSE).

Syntax

```
ST_Within(g1 ST_Geometry, g2 ST_Geometry)
```

Return type

BOOLEAN

Example

In the example, two tables are created: **buildingfootprints** contains a city's building footprints, while the other, **lots**, contains its lots. The city engineer wants to make sure that all the building footprints are completely inside their lots.

In both tables the ST_MultiPolygon data type stores the ST_Geometry of the building footprints and the lots. The database designer selected ST_MultiPolygon for both features because a lot can be separated by a natural feature such as a river, and a building footprint can be made up of several buildings:

```
CREATE TABLE buildingfootprints (building_id integer,  
                                lot_id       integer,  
                                footprint    ST_MultiPolygon);
```

```
CREATE TABLE lots (lot_id integer,  
                   lot     ST_MultiPolygon);
```

The city engineer first retrieves the buildings that are not completely within a lot:

```
SELECT building_id
       FROM buildingfootprints, lots
       WHERE ST_Within(footprint,lot);
```

```
building_id
           506
           543
           178
```

The city engineer realizes that although the first query produces a list of all building IDs that have footprints outside a lot polygon, it does not ascertain whether the rest have the correct **lot_id** assigned to them. This second query performs a data integrity check on the **lot_id** column of the **buildingfootprints** table:

```
SELECT bf.building_id, bf.lot_id bldg_lot_id, lots.lot_id lots_lot_id
       FROM buildingfootprints bf, lots
       WHERE ST_Within(footprint,lot)
       AND lots.lot_id <> bf.lot_id;
```

```
building_id bldg_lot_id lots_lot_id
           178           5192           203
```

Related reference:

- “The ST_Within() function” on page 7-5
- “The ST_Within() function” on page 7-20

The ST_WKBToSQL() function

The **ST_WKBToSQL()** function constructs an ST_Geometry given its well-known binary representation. The SRID of the ST_Geometry is 0.

Syntax

```
ST_WKBToSQL(WKBGeometry lvarchar)
```

Return type

ST_Geometry

Example

The following CREATE TABLE statement creates the **lots** table, which has two columns: **lot_id**, which uniquely identifies each lot, and the **lot** polygon column, which contains the geometry of each lot:

```
CREATE TABLE lots (lot_id integer,
                   lot      ST_MultiPolygon);
```

The following C code fragment contains ODBC functions included with the spatial data type functions that insert data into the **lots** table.

The **ST_WKBToSQL()** function converts WKB representations into IBM Informix spatial geometry. The entire INSERT statement is copied into the *sql_stmt* string. The INSERT statement contains parameter markers to accept the **lot_id** data and the **lot** data, dynamically:

```

/* Create the SQL insert statement to populate the lots table.
 * The question marks are parameter markers that indicate the
 * column values that will be inserted at run time. */
sprintf(sql_stmt,
        "INSERT INTO lots (lot_id, lot) "
        "VALUES (?, ST_WKBTToSQL(?))");

/* Prepare the SQL statement for execution */
rc = SQLPrepare (hstmt, (unsigned char *)sql_stmt, SQL_NTS);

/* Bind the lot_id to the first parameter. */
pcbvalue1 = 0;
rc = SQLBindParameter (hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                      SQL_INTEGER, 0, 0,
                      &lot_id, 0, &pcbvalue1);

/* Bind the lot geometry to the second parameter. */
pcbvalue2 = lot_wkb_len;
rc = SQLBindParameter (hstmt, 2, SQL_PARAM_INPUT, SQL_C_BINARY,
                      SQL_INFX_UDT_LVARCHAR, lot_wkb_len, 0,
                      lot_wkb_buf, lot_wkb_len, &pcbvalue2);

/* Execute the insert statement. */
rc = SQLExecute (hstmt);

```

The ST_WKTTToSQL() function

The **ST_WKTTToSQL()** function constructs an **ST_Geometry** given its well-known text representation. The SRID of the **ST_Geometry** is 0.

Syntax

ST_WKTTToSQL (WKT lvarchar)

Return type

ST_Geometry

Example

The following **CREATE TABLE** statement creates the **geometry_test** table, which contains two columns: **gid**, of type **INTEGER**, which uniquely identifies each row, and the **g1** column, which stores the geometry:

```

CREATE TABLE geometry_test (gid integer,
                             g1 ST_Geometry);

```

The following **INSERT** statements insert the data into the **gid** and **g1** columns of the **geometry_test** table. The **ST_WKTTToSQL()** function converts the text representation of each geometry into its corresponding IBM Informix Spatial DataBlade Module instantiable subclass:

```

INSERT INTO geometry_test VALUES(
    1,
    ST_WKTTToSQL('point (10.02 20.01)')
);

INSERT INTO geometry_test VALUES(
    2,
    ST_WKTTToSQL('linestring (10.02 20.01,10.01 30.01,10.01 40.01)')
);

INSERT INTO geometry_test VALUES(
    3,

```

```

        ST_WKTToSQL('polygon ((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01))')
    );

INSERT INTO geometry_test VALUES(
    4,
    ST_WKTToSQL('multipoint (10.02 20.01,10.32 23.98,11.92 35.64)')
);

INSERT INTO geometry_test VALUES(
    5,
    ST_WKTToSQL('multilinestring ((10.02 20.01,10.32 23.98,11.92
25.64),(9.55 23.75,15.36 30.11))')
);

INSERT INTO geometry_test VALUES(
    6,
    ST_WKTToSQL('multipolygon (((10.02 20.01,11.92 35.64,25.02
34.15,19.15 33.94,10.02 20.01)),((51.71 21.73,73.36 27.04,71.52
32.87,52.43 31.90,51.71 21.73)))')
);

```

The ST_X() function

The **ST_X()** function returns the X coordinate of a point.

Syntax

```
ST_X(pt1 ST_Point)
```

Return type

DOUBLE PRECISION

Example

The **x_test** table is created with two columns: **gid**, which uniquely identifies the row, and the **pt1** point column:

```
CREATE TABLE x_test (gid integer,
                    pt1 ST_Point);
```

The following INSERT statements insert two rows. One is a point without a Z coordinate or a measure. The other column has both a Z coordinate and a measure:

```
INSERT INTO x_test VALUES(
    1,
    ST_PointFromText('point (10.02 20.01)', 1000)
);

INSERT INTO x_test VALUES(
    2,
    ST_PointFromText('point zm (10.02 20.01 5.0 7.0)', 1000)
);
```

The query retrieves the values in the **gid** column and the DOUBLE PRECISION X coordinate of the points:

```
SELECT gid, ST_X(pt1) x_coord
FROM x_test;

    gid      x_coord
-----
1 10.0200000000
2 10.0200000000
```

The ST_Y() function

The **ST_Y()** function returns the Y coordinate of a point.

Syntax

```
ST_Y(p1 ST_Point)
```

Return type

DOUBLE PRECISION

Example

The **y_test** table is created with two columns: **gid**, which uniquely identifies the row, and the **pt1** point column:

```
CREATE TABLE y_test (gid integer,
                    pt1 ST_Point);
```

The following INSERT statements insert two rows. One is a point without a Z coordinate or a measure. The other has both a Z coordinate and a measure:

```
INSERT INTO y_test VALUES(
    1,
    ST_PointFromText('point (10.02 20.01)', 1000)
);

INSERT INTO y_test VALUES(
    2,
    ST_PointFromText('point zm (10.02 20.01 5.0 7.0)',1000)
);
```

The query retrieves the values in the **gid** column and the DOUBLE PRECISION Y coordinate of the points:

```
SELECT gid, ST_Y(pt1) y_coord
FROM y_test;
```

gid	y_coord
1	20.010000000000
2	20.010000000000

The ST_Z function

The **ST_Z()** function returns the Z coordinate of a point.

Syntax

```
ST_Z(p1 ST_Point)
```

Return type

DOUBLE PRECISION

Example

The **z_test** table is created with two columns: **gid**, which uniquely identifies the row, and the **pt1** point column:

```
CREATE TABLE z_test (gid integer,
                    pt1 ST_Point);
```

The following INSERT statements insert two rows. One is a point without a Z coordinate or a measure. The other has both a Z coordinate and a measure:

```
INSERT INTO z_test VALUES(
  1,
  ST_PointFromText('point (10.02 20.01)', 1000)
);

INSERT INTO z_test VALUES(
  2,
  ST_PointFromText('point zm (10.02 20.01 5.0 7.0)', 1000)
);
```

The query retrieves the values in the **gid** column and the DOUBLE PRECISION Z coordinate of the points. The first row is NULL because the point does not have a Z coordinate:

```
SELECT gid, ST_Z(pt1) z_coord
FROM z_test;
```

gid	z_coord
1	
2	5.000000000000

Appendix A. Load and unload shapefile data

Use the **infoshp**, **loadshp**, and **unloadshp** utilities for working with spatial data contained in ESRI shapefiles.

The executable files for the utilities are located in the `$INFORMIXDIR/extend/spatial.version/bin` directory:

- The **infoshp** utility is useful for gathering information from ESRI shapefiles when you are preparing to load the shapefiles into a database.
- The **loadshp** utility loads spatial data from an ESRI shapefile into the database.
- The **unloadshp** utility copies data from the database to an ESRI shapefile.

You can leave them in this directory, or you can copy them to `$INFORMIXDIR/bin`. If you leave them here, you may want to add `$INFORMIXDIR/extend/spatial.version/bin` to your **\$PATH** environment variable. If you copy the files to `$INFORMIXDIR/bin`, you may not need to change your **\$PATH** environment variable, if `$INFORMIXDIR/bin` is already included in the variable definition.

Important: The **loadshp** utility does not add information to ESRI system tables, such as the **layers** table. Therefore, data loaded with the **loadshp** utility is not accessible to ArcSDE and other ESRI client tools. Use the ESRI **shp2sde** command to load data if you want to access it using ESRI client tools. Data loaded using the **loadshp** utility is accessible to client programs that do not depend on ESRI system tables other than the OGC-standard **geometry_columns** and **spatial_references** tables.

Related reference:

“Insert data into a spatial column” on page 1-9

“Create a spatial index” on page 1-11

The infoshp utility

The **infoshp** utility reports information extracted from headers of the `.shp`, `.shx`, and `.dbf` files that make up ESRI shapefiles. It also detects the presence of optional `.prj` files that may be associated with ESRI shapefiles and reports the coordinate system information. The **infoshp** utility can check for **spatial_references** table entries that are qualified to load one or more shapefiles. If no spatial reference exists that can be used to load the specified shapefiles, the **infoshp** utility can create a new entry in the **spatial_references** table for loading the shapefiles.

Syntax

```
►► infoshp [-o] Info Info [-f filename] ►►
```

Info Info::

Operation modes

You use the **-o** flag to set the operation mode for the **infoshp** command. Set the **-o** flag to one of the following options:

- check** Checks for **spatial_references** table entries that are qualified to load the specified shapefiles.
- create** Creates a new entry in the **spatial_references** table for loading the specified shapefiles.
- info** Reports information extracted from the headers of the **.shp**, **.shx**, **.dbf**, and optional **.prj** files associated with the specified shapefiles.

Command-line switches

You can use the **infoshp** command flags to specify the following options.

- D** The database name
- f** The path and name of one or more ESRI shapefiles to process
- p** (optional) The IBM Informix password
If you specify the **-p** option, you must also specify the **-u** option.
- s (optional)**
The IBM Informix server
Defaults to the value of the **INFORMIXSERVER** environment variable
- u (optional)**
The IBM Informix user name
If you specify the **-u** option, you must also specify the **-p** option.
- V** Prints version information for this utility

The loadshp utility

The **loadshp** utility loads spatial features and associated attributes from an ESRI shapefile into a table in an IBM Informix database.

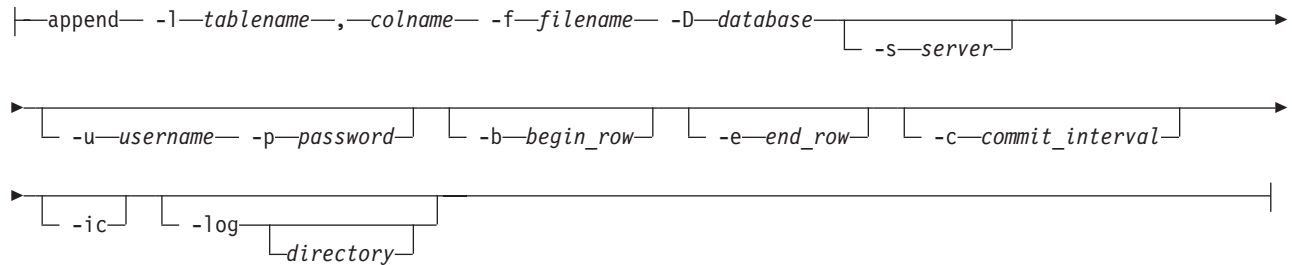

When **loadshp** creates a table, it inserts a row into the **geometry_columns** system table. When you want to drop a table created by **loadshp**, you should also delete the corresponding row from the **geometry_columns** table.

Tip: The **loadshp** utility creates a primary key constraint on the **se_row_id** column of the table that you are loading.

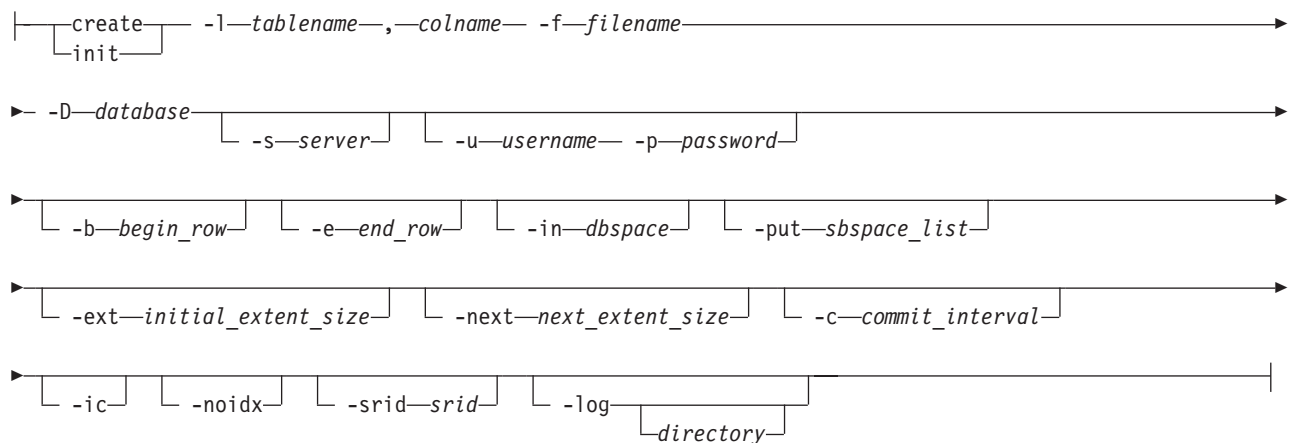

Syntax

Append mode:

Init and create mode:

SQL mode:

Operation modes

You use the **-o** flag to set the operation mode for the **loadshp** command. Set the **-o** flag to one of the following options:

append

Spatial features are added to the table specified by the **-l** flag. The structure of the existing database table must match the structure of a table derived

from information specified by the **-I** command-line option and from metadata stored in the shapefile's associated `.dbf` file.

- create** Spatial features are loaded into a newly created database table. An error is returned if a table with the name specified by the **-I** flag already exists. The structure of the new table is derived from the table name and column name specified by the **-I** command-line option as well as from metadata stored in the shapefile's associated `.dbf` file.
- init** The table specified by the **-I** flag is first dropped and then spatial features are loaded into a newly created table of the same name.
- sql** The following SQL statements are displayed on the console (and can be logged to a file):
- DROP TABLE ...
 - DELETE FROM **geometry_columns** ...
 - CREATE TABLE ...
 - INSERT INTO **geometry_columns** ...
 - CREATE UNIQUE INDEX ... USING btree;
 - ALTER TABLE ... ADD CONSTRAINT PRIMARY KEY (se_row_id) ...
 - CREATE INDEX ... USING rtree;
 - UPDATE STATISTICS ...

The structure of the table to be loaded is derived from information specified by the **-I** command-line option and from metadata stored in the shapefile's associated `.dbf` file containing feature attributes.

Command-line switches

You can use the **loadshp** command-line switches to specify the following options.

-b (optional)

The first row in the shapefile to load

-c (optional)

The number of rows to load before committing work and beginning a new transaction

Defaults to 1000 rows

If you are loading data into a database that does not have transaction logging enabled, the commit interval determines how frequently information messages are displayed on the console.

-D The database name

-e (optional)

The last row in the shapefile to load

-ext (optional)

Specifies the initial extent size for the table to be loaded

This option is not valid in the **append** option of the **-o** flag.

-f The path and name of the ESRI shapefile to be loaded

-ic (optional)

Specifies use of an INSERT CURSOR

Using an INSERT CURSOR to load data significantly reduces load time, but limits the client program's ability to handle errors. INSERT CURSORS

buffer rows before writing them to the database to improve performance. If an error is encountered during the load, all buffered rows following the last successfully inserted row are discarded.

-in (optional)

Specifies the dbspace in which to create the table to be loaded

This option is not valid in the **append** option of the **-o** flag.

-l The table and geometry column to load data into

-log (optional)

Specifies whether to write information about the status of data loading to a log file

The log file has the same name as the shapefile you are loading from with the extension `.log`.

If you do not specify a directory, the log file is created in the same directory as the shapefile you are loading from.

-next Specifies the next extent size for the table to be loaded

This option is not valid in the **append** option of the **-o** flag.

-noidx (optional)

Specifies that indexes should not be built and statistics should not be updated after the shapefile data has been loaded

Unless this option is specified when executing **loadshp -o create** or **loadshp -o init**, a unique B-tree index is built on the **se_row_id** column, an R-tree index is built on the **geometry** column, and statistics are updated for the table after the shapefile data has been loaded.

-p (optional)

The IBM Informix password

If you specify the **-p** option, you must also specify the **-u** option.

-put (optional)

Specifies the sbspaces in which large shapes inserted into the load table's geometry column will be stored

Multiple sbspaces names must be separated by commas and no white space must appear in the list of sbspaces names. This option is not valid with the **append** option of the **-o** flag.

-s (optional)

The IBM Informix server

Defaults to the value of the `INFORMIXSERVER` environment variable.

-srid (optional)

The spatial reference ID for the data you are loading

The integer you specify must exist as a spatial reference ID in the **spatial_references** table. If you do not specify the **-srid** command-line option, the spatial reference ID defaults to 0.

-u (optional)

The IBM Informix user name

If you specify the **-u** option, you must also specify the **-p** option.

-V Prints version information for this utility

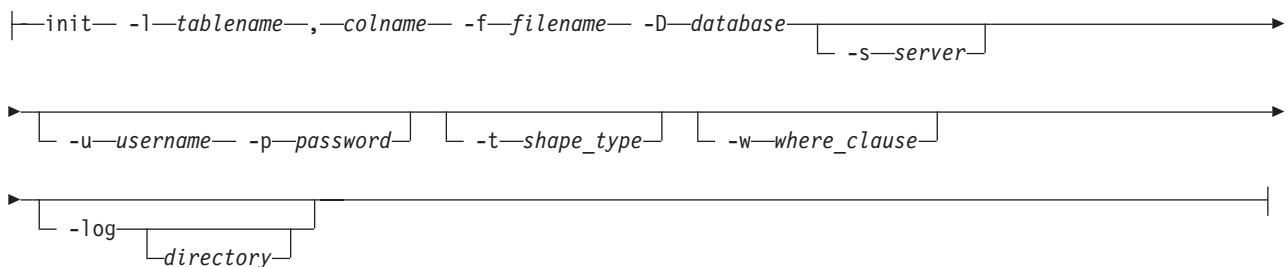

The unloadshp utility

The **unloadshp** utility copies spatial features and associated attributes from a table in an IBM Informix database into an ESRI shapefile.

Syntax

Init mode:

Append mode:

Operation modes

You use the **-o** flag to set the operation mode for the **unloadshp** command. Set the **-o** flag to one of the following options:

append

Spatial features are appended to the existing ESRI shapefile specified by the **-f** option.

init Spatial features are unloaded into a newly created ESRI shapefile.

Command-line switches

You can use the **unloadshp** command flags to specify the following options.

-D The database name

-f The path and name of the shapefile

-l The table and geometry column from which to extract data

The table and column must exist, and the executing user must either own the table or have access to it.

-log (optional)

Specifies whether to write information about the status of data loading to a log file

The log file has the same name as the shapefile you are loading into with the extension .log.

If you do not specify a directory, the log file is created in the same directory as the shapefile you are loading.

-p (optional)

The IBM Informix password

If you specify the **-p** option, you must also specify the **-u** option.

-s (optional)

The IBM Informix server

Defaults to the value of the INFORMIXSERVER environment variable.

-t (optional)

An integer indicating the type of shape to extract and write to the ESRI shapefile

The possible values are:

- 1 Point
- 2 PolyLine
- 5 Polygon
- 8 Multipoint
- 9 PointZ
- 10 PolyLineZ
- 11 PointZM
- 13 PolyLineZM
- 15 PolygonZM
- 18 MultiPointZM
- 19 PolygonZ
- 20 MultiPointZ
- 21 PointM
- 23 PolyLineM
- 25 PolygonM
- 28 MultiPointM

If you do not specify the **-t** option, the type defaults to the type of the first shape retrieved from the database table.

-u (optional)

The IBM Informix user name

If you specify the **-u** option, you must also specify the **-p** option.

-V Prints version information for this utility

-w (optional)

(optional) The SQL WHERE clause to qualify the data extracted from the table

Enclose the WHERE clause in double quotation marks and enclose any string literals within the clause in single quotation marks. Omit the keyword WHERE.

Appendix B. OGC well-known text representation of spatial reference systems

These topics explain how to represent a spatial reference system using a text string and provides information about supported units of measure, spheroids, datums, prime meridians, and projections.

The information provided in these topics is primarily intended for use with the **ST_Transform()** function.

Related reference:

“The ST_Transform() function” on page 8-109

The text representation of a spatial system

The well-known text representation of spatial reference systems provides a standard textual representation for spatial reference system information.

The definitions of the well-known text representation are modeled after the POSC/EPSS coordinate system data model.

A spatial reference system, also referred to as a coordinate system, is a geographic (latitude, longitude), a projected (X,Y), or a geocentric (X, Y, Z) coordinate system.

A coordinate system is composed of several objects. Each object is defined by an uppercase keyword (for example, DATUM or UNIT) followed by the defining, comma-delimited parameters of the object in brackets. Some objects are composed of other objects.

Implementations are free to substitute standard brackets () for square brackets [] and should be prepared to read both forms of brackets.

The Extended Backus Naur Form (EBNF) definition for the string representation of a coordinate system is as follows, using square brackets:

```
<coordinate system> = <projected cs> | <geographic cs>
  | <geocentric cs>
<projected cs> = PROJCS["<name>", <geographic cs>,
  <projection>, {<parameter>,*} <linear unit>]
<projection> = PROJECTION["<name>"]
<parameter> = PARAMETER["<name>", <value>]
<value> = <number>
```

A coordinate system of a data set is identified by one of the following three keywords:

PROJCS

if the data is in projected coordinates

GEOGCS

if in geographic coordinates

GEOCCS

if in geocentric coordinates

The PROJCS keyword is followed by all of the pieces that define the projected coordinate system. The first piece of any object is always the name. Several objects follow the name: the geographic coordinate system, the map projection, one or more parameters, and the linear unit of measure.

As an example, UTM zone 10N on the NAD83 datum is defined as:

```
PROJCS["NAD_1983_UTM_Zone_10N",
  <geographic cs>,
  PROJECTION["Transverse_Mercator"],
  PARAMETER["False_Easting",500000.0],
  PARAMETER["False_Northing",0.0],
  PARAMETER["Central_Meridian",-123.0],
  PARAMETER["Scale_Factor",0.9996],
  PARAMETER["Latitude_of_Origin",0.0],
  UNIT["Meter",1.0]]
```

The name and several objects define the geographic coordinate system object: the datum, the prime meridian, and the angular unit of measure:

```
<geographic cs> = GEOGCS["<name>", <datum>, <prime meridian>, <angular unit>]
```

```
<datum> = DATUM["<name>", <spheroid>]
```

```
<spheroid> = SPHEROID["<name>", <semi-major axis>,
  <inverse flattening>]
```

```
<semi-major axis> = <number>
```

NOTE: semi-major axis is measured in meters and must be > 0.

```
<inverse flattening> = <number>
```

```
<prime meridian> = PRIMEM["<name>", <longitude>]
```

```
<longitude> = <number>
```

The geographic coordinate system string for UTM zone 10N on NAD83 is:

```
GEOGCS["GCS_North_American_1983",
  DATUM["D_North_American_1983",
  SPHEROID["GRS_1980",6378137,298.257222101]],
  PRIMEM["Greenwich",0],
  UNIT["Degree",0.0174532925199433]]
```

The UNIT object can represent angular or linear units of measure:

```
<angular unit> = <unit>
```

```
<linear unit> = <unit>
```

```
<unit> = UNIT["<name>", <conversion factor>]
```

```
<conversion factor> = <number>
```

The conversion factor specifies the number of meters (for a linear unit) or the number of radians (for an angular unit) per unit and must be greater than zero.

Therefore, the full string representation of UTM zone 10N is:

```
PROJCS["NAD_1983_UTM_Zone_10N",
  GEOGCS["GCS_North_American_1983",
    DATUM["D_North_American_1983",SPHEROID["GRS_1980",6378137,298.257222101]],
    PRIMEM["Greenwich",0],UNIT["Degree",0.0174532925199433]],
  PROJECTION["Transverse_Mercator"],PARAMETER["False_Easting",500000.0],
  PARAMETER["False_Northing",0.0],PARAMETER["Central_Meridian",-123.0],
  PARAMETER["Scale_Factor",0.9996],PARAMETER["Latitude_of_Origin",0.0],
  UNIT["Meter",1.0]]
```

A geocentric coordinate system is quite similar to a geographic coordinate system. It is represented by:

```
<geocentric cs> = GEOCCS[ "<name>", <datum>, <prime meridian>, <linear unit> ]
```

You can use the **SE_CreateSrtext()** function to assist you in constructing these spatial reference system text strings.

The remainder of this appendix shows the OGC well-known text “building blocks” of spatial reference systems that are supported by the IBM Informix spatial data types.

These text strings can be generated by the **SE_CreateSrtext()** function; you use the factory ID number in the first column of the table as the input argument to **SE_CreateSrtext()**.

Angular units

IBM Informix spatial data types support many angular units.

The following table shows a representative sample of the angular units of measure supported by the IBM Informix spatial data types. For a complete list of supported angular units of measure, see the file `INFORMIXDIR/extend/spatial.version/include/pedef.h`.

Table B-2. Angular units

Factory ID	Description	OGC well-known text string
9101	Radian	UNIT["Radian",1]
9102	Degree	UNIT["Degree",0.0174532925199433]
9103	Arc-minute	UNIT["Minute",0.0002908882086657216]
9104	Arc-second	UNIT["Second",4.84813681109536E-06]
9105	Grad (angle subtended by 1/400 circle)	UNIT["Grad",0.01570796326794897]
9106	Gon (angle subtended by 1/400 circle)	UNIT["Gon",0.01570796326794897]
9109	Microradian (1e-6 radian)	UNIT["Microradian",1E-06]
9112	Centesimal minute (1/100th Gon (Grad))	UNIT["Minute_Centesimal",0.0001570796326794897]
9113	Centesimal second(1/10000th Gon (Grad))	UNIT["Second_Centesimal",1.570796326794897E-06]
9114	Mil (angle subtended by 1/6400 circle)	UNIT["Mil_6400",0.0009817477042468104]

Geodetic spheroids

IBM Informix spatial data types support many geodetic spheroids.

The following table lists a representative sample of the geodetic spheroids supported by the IBM Informix spatial data types. For a complete list of supported geodetic spheroids, see the file `INFORMIXDIR/extend/spatial.version/include/pedef.h`.

Appendix C. OGC well-known text representation of geometry

Each geometry type has a well-known text representation from which new instances can be constructed or existing instances can be converted to textual form for alphanumeric display.

“Well-known binary representation” on page 3-1

Well-known text representation in a C program

The well-known text representation of geometry can be incorporated into a C program. The structure for such an implementation is defined below. The notation {}* denotes zero or more repetitions of the tokens within the braces. The braces do not appear in the output token list.

```
<Geometry Tagged Text> :=
    <Point Tagged Text>
  | <LineString Tagged Text>
  | <Polygon Tagged Text>
  | <MultiPoint Tagged Text>
  | <MultiLineString Tagged Text>
  | <MultiPolygon Tagged Text>

<Point Tagged Text> :=
    POINT <Point Text>
<LineString Tagged Text> :=
    LINESTRING <LineString Text>
<Polygon Tagged Text> :=
    POLYGON <Polygon Text>
<MultiPoint Tagged Text> :=
    MULTIPOINT <Multipoint Text>
<MultiLineString Tagged Text> :=
    MULTILINESTRING <MultiLineString Text>
<MultiPolygon Tagged Text> :=
    MULTIPOLYGON <MultiPolygon Text>

<Point Text> := EMPTY
  | <Point>
  | Z <PointZ>
  | M <PointM>
  | ZM <PointZM>

<Point> := <x> <y>
  <x> := double precision literal
  <y> := double precision literal

<PointZ> := <x> <y> <z>
  <x> := double precision literal
  <y> := double precision literal
  <z> := double precision literal

<PointM> := <x> <y> <m>
  <x> := double precision literal
  <y> := double precision literal
  <m> := double precision literal

<PointZM> := <x> <y> <z> <m>
```

```

<x> := double precision literal
<y> := double precision literal
<z> := double precision literal
<m> := double precision literal

```

```

<LineString Text> := EMPTY
| ( <Point Text > {, <Point Text> }* )
| Z ( <PointZ Text > {, <PointZ Text> }* )
| M ( <PointM Text > {, <PointM Text> }* )
| ZM ( <PointZM Text > {, <PointZM Text> }* )

```

```

<Polygon Text> := EMPTY
| ( <LineString Text > {, <LineString Text > }* )

```

```

<Multipoint Text> := EMPTY
| ( <Point Text > {, <Point Text > }* )

```

```

<MultiLineString Text> := EMPTY
| ( <LineString Text > {, <LineString Text> }* )

```

```

<MultiPolygon Text> := EMPTY
| ( < Polygon Text > {, < Polygon Text > }* )

```

Well-known text representation in an SQL editor

Since the well-known text representation is text, it can be typed into an SQL script or directly into an SQL editor. The text is converted to and from a geometry by a function. Functions that convert text to geometry have the following syntax:

```
function ('text description',SRID)
```

Example:

```
ST_PointFromText('point zm (10.01 20.04 3.2 9.5)', 1)
```

The spatial reference identifier, SRID—the primary key to the **spatial_references** table—identifies the possible spatial reference systems within an IBM Informix instance. An SRID is assigned to a spatial column when it is created. Before a geometry can be inserted into a spatial column, its SRID must match the SRID of the spatial column.

The *text description* is made up of three basic components enclosed in single quotation marks:

```
'geometry type [coordinate type] [coordinate list]'
```

The *geometry type* is defined as one of the following: point, linestring, polygon, multipoint, multilinestring, or multipolygon.

The *coordinate type* specifies whether the geometry has Z coordinates or measures. Leave this argument blank if the geometry has neither; otherwise, set the coordinate type to Z for geometries containing Z coordinates, M for geometries with measures, and ZM for geometries that have both.

The *coordinate list* defines the double-precision vertices of the geometry. Coordinate lists are comma-delimited and enclosed by parentheses. Geometries having multiple components require sets of parentheses to enclose each component part. If the geometry is empty, the EMPTY keyword replaces the coordinates.

The following examples provide a complete list of all possible permutations of the text description portion of the text representation.

Geometry type	Text description	Comment
ST_Point	'point empty'	Empty point
ST_Point	'point z empty'	Empty point with Z coordinate

ST_MultiPolygon	'multipolygon m (((10 10 2, 10 20 3, 20 20 4, 20 15 5, 10 10 2), (50 40 7, 50 50 3, 60 50 4, 60 40 5, 50 40 7)))'	Multipolygon with measures
ST_MultiPolygon	'multipolygon zm (((10 10 7 2, 10 20 8 3, 20 20 7 4, 20 15 5 5, 10 10 7 2), (50 40 6 7, 50 50 6 3, 60 50 5 4, 60 40 6 5, 50 40 7 7)))'	Multipolygon with Z coordinates and measures

Modified well-known text representation

The IBM Informix software provides an additional modified well-known text representation for loading text strings directly into geometry columns without filtering the string through one of the Spatial DataBlade text functions. By placing the SRID in front of the text description, you can insert the resulting text string directly into a spatial column. The load statement in the DB-Access utility reads text files generated with this format and inserts the modified well-known text representation into the geometry columns.

To create a modified well-known text representation, remove the quotations and precede the text description with the SRID separated by a space.

For example, the well-known text representation of a point in the **ST_PointFromText()** function:

```
ST_PointFromText('Point zm (10.98 29.91 10.2 9.1)',1)
```

converts to:

```
1 ST_Point zm(10.98 29.91 10.2 9.1)
```

You can write the modified text string into a file and separate it from other column values by the standard delimiter.

Appendix D. OGC well-known binary representation of geometry

The well-known binary representation for OGC geometry (WKBGeometry), provides a portable representation of a geometry value as a contiguous stream of bytes. It permits geometry values to be exchanged between a client application and an SQL database in binary form.

The well-known binary representation for geometry is obtained by serializing a geometry instance as a sequence of numeric types drawn from the set {Unsigned Integer, Double} and then serializing each numeric type as a sequence of bytes using one of two well-defined, standard binary representations for numeric types (NDR, XDR). The specific binary encoding used for a geometry byte stream is described by a one-byte tag that precedes the serialized bytes. The only difference between the two encodings of geometry is byte order. The XDR encoding is big endian, while the NDR encoding is little endian.

Numeric type definitions

An 'unsigned integer' is a 32-bit (4 byte) data type that encodes a nonnegative integer in the range [0, 4294967295].

A 'double' is a 64-bit (8 byte) double-precision data type that encodes a double-precision number using the IEEE 754 double-precision format.

The above definitions are common to both XDR and NDR.

XDR (big endian) encoding of numeric types

The XDR representation of an unsigned integer is big endian (most significant byte first).

The XDR representation of a double is big endian (sign bit is first byte).

NDR (little endian) encoding of numeric types

The NDR representation of an unsigned integer is little endian (least significant byte first).

The NDR representation of a double is little endian (sign bit is last byte).

Conversion between the NDR and XDR representations of WKB geometry

Conversion between the NDR and XDR data types for unsigned integers and doubles is a simple operation involving reversing the order of bytes within each unsigned integer or double in the byte stream.

Description of WKBGeometry byte streams

The well-known binary representation for geometry is described below. The basic building block is the byte stream for a point that consists of two doubles. The byte streams for other geometries are built using the byte streams for geometries that have already been defined.

Important: These structures are only intended to define the stream of bytes that is transmitted between the client and server. They should not be used as C-language data structures. See the following figure for an example of such a byte stream.

```
// Basic Type definitions
// byte : 1 byte
// uint32 : 32 bit unsigned integer (4 bytes)
// double : double precision number (8 bytes)

// Building Blocks : Point, LinearRing
Point {
    double x;
    double y;
    double z;
    double m;
};

LinearRing {
    uint32 numPoints;
    Point points[numPoints];
}

enum wkbGeometryType {
    wkbPoint = 1,
    wkbLineString = 2,
    wkbPolygon = 3,
    wkbMultiPoint = 4,
    wkbMultiLineString = 5,
    wkbMultiPolygon = 6,
    wkbGeometryCollection = 7,
    wkbPointZ = 1001,
    wkbLineStringZ = 1002,
    wkbPolygonZ = 1003,
    wkbMultiPointZ = 1004,
    wkbMultiLineStringZ = 1005,
    wkbMultiPolygonZ = 1006,
    wkbGeometryCollectionZ = 1007,
    wkbPointM = 2001,
    wkbLineStringM = 2002,
    wkbPolygonM = 2003,
    wkbMultiPointM = 2004,
    wkbMultiLineStringM = 2005,
    wkbMultiPolygonM = 2006,
    wkbGeometryCollectionM = 2007,
    wkbPointZM = 3001,
    wkbLineStringZM = 3002,
    wkbPolygonZM = 3003,
    wkbMultiPointZM = 3004,
    wkbMultiLineStringZM = 3005,
    wkbMultiPolygonZM = 3006,
    wkbGeometryCollectionZM = 3007
};

enum wkbByteOrder {
    wkbXDR = 0, // Big Endian
    wkbNDR = 1 // Little Endian
};

WKBPoint {
```

```

    byte    byteOrder;
    uint32  wkbType;           // 1
    Point   point;
}

WKBLineString {
    byte    byteOrder;
    uint32  wkbType;           // 2
    uint32  numPoints;
    Point   points[numPoints];
}

        WKBGeometryCollection collection;
        WKBMultiPoint  mpoint;
        WKBMultiLineString mlinestring;
        WKBMultiPolygon mpolygon;
    }
};

WKBGeometryCollection {
    byte    byte_order;
    uint32  wkbType;           // 7
    uint32  num_wkbGeometries;
    WKBGeometry wkbGeometries[num_wkbGeometries]
}

```

Figure D-1. Well-known binary representation for a geometry object in NDR format(B=1) of type polygon (T=3) with two rings (NR = 2) and each ring having three points (NP = 3)

The number of bytes in each box is shown:

1	4	4	4	8	8	8	8	8	8	4	8	8	8	8	8	8
---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---	---

Assertions for well-known binary representation for geometry

The well-known binary representation for geometry is designed to represent instances of the geometry types described in the geometry object model and in the *OpenGIS Abstract Specification*.

These assertions imply the following:

Linear rings

Rings are simple and closed, which means that linear rings may not self intersect.

Polygons

No two linear rings in the boundary of a polygon may cross each other. The linear rings in the boundary of a polygon may intersect, at most, at a single point but only as a tangent.

Multipolygons

The interiors of two polygons that are elements of a multipolygon may not intersect. The boundaries of any two polygons that are elements of a multipolygon may touch at only a finite number of points.

Appendix E. ESRI shape representation

The ESRI shape representation is an industry standard format that is used in ESRI shape files. You can use the **SE_AsShape()** function to retrieve geometries from a table in shape format. You can insert shape format data into database tables by using the **SE_GeomFromShape()**, **SE_PointFromShape()**, **SE_PolyFromShape()**, and other similar functions. All functions are described in detail in Chapter 8, “Spatial functions,” on page 8-1.

These topics provide background information about the ESRI shape representation.

“ESRI shape representation” on page 3-2

Shape type values

A shape type of 0 indicates a null shape with no geometric data for the shape.

Value	Shape type	Spatial data type
0	Null Shape	Empty ST_Geometry
1	Point	ST_Point
3	PolyLine	ST_MultiLineString
5	Polygon	ST_MultiPolygon
8	MultiPoint	ST_MultiPoint
9	PointZ	ST_Point with Z coordinates
10	PolyLineZ	ST_MultiLineString with Z coordinates
11	PointZM	ST_Point with Z coordinates and measures
13	PolyLineZM	ST_MultiLineString with Z coordinates and measures
15	PolygonZM	ST_MultiPolygon with Z coordinates and measures
18	MultiPointZM	ST_MultiPoint with Z coordinates and measures
19	PolygonZ	ST_MultiPolygon with Z coordinates
20	MultiPointZ	ST_MultiPoint with Z coordinates
21	PointM	ST_Point with measures
23	PolyLineM	ST_MultiLineString with measures
25	PolygonM	ST_MultiPolygon with measures
28	MultiPointM	ST_MultiPoint with measures

Shape types not specified above (2, 4, 6, and so on) are reserved for future use.

The ST_LineString and ST_Polygon Spatial data types do not have equivalent shape type values.

Shape types in XY space

These topics describe shapes with X and Y coordinates.

Point

A Point consists of a pair of double-precision coordinates in the order X, Y. The following table shows Point byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	1	Integer	1	Little endian
Byte 4	X	X	Double	1	Little endian
Byte 12	Y	Y	Double	1	Little endian

MultiPoint

A MultiPoint consists of a collection of points. The bounding box is stored in the order Xmin, Ymin, Xmax, Ymax. The following table shows MultiPoint byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	8	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumPoints	NumPoints	Integer	1	Little endian
Byte 40	Points	Points	Point	NumPoints	Little endian

PolyLine

A PolyLine is an ordered set of vertices that consists of one or more parts. A part is a connected sequence of two or more points. Parts may be connected to and may intersect one another.

Because this specification does not forbid consecutive points with identical coordinates, shapefile readers must handle such cases. On the other hand, the degenerate zero length parts that might result are not allowed.

The following fields are for a PolyLine:

Box The bounding box for the PolyLine, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts

The number of parts in the PolyLine

NumPoints

The total number of points for all parts

Parts An array of length NumParts. Stores, for each PolyLine, the index of its first point in the points array

Array indexes are numbered with respect to 0.

Points An array of length NumPoints

The points for each part in the PolyLine are stored end to end. The points for part 2 follow the points for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the points array between parts.

The following table shows PolyLine byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	3	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian

Position	Field	Value	Type	Number	Byte order
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian

Tip: $X = 44 + (4 \cdot \text{NumParts})$

Polygon

A polygon consists of one or more rings. A ring is a connected sequence of four or more points that form a closed, non-self-intersecting loop. A polygon may contain multiple outer rings. The order of vertices or orientation for a ring indicates which side of the ring is the interior of the polygon. The neighborhood to the right of an observer walking along the ring in vertex order is the neighborhood inside the polygon. Vertices of rings defining holes in polygons are in a counterclockwise direction. Vertices for a single, ringed polygon are, therefore, always in clockwise order. The rings of a polygon are referred to as its parts.

Because this specification does not forbid consecutive points with identical coordinates, shapefile readers must handle such cases. On the other hand, the degenerate zero length or zero area parts that might result are not allowed.

The following fields are for a polygon:

Box The bounding box for the polygon, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts

The number of rings in the polygon

NumPoints

The total number of points for all rings

Parts An array of length NumParts.

Stores, for each ring, the index of its first point in the points array. Array indexes are numbered with respect to 0.

Points An array of length NumPoints

The points for each ring in the polygon are stored end to end. The points for ring 2 follow the points for ring 1, and so on. The parts array holds the array index of the starting point for each ring. There is no delimiter in the points array between rings.

The following are important notes about polygon shapes:

- The rings are closed (the first and last vertex of a ring must be the same).
- The order of rings in the points array is not significant.
- Polygons stored in a shapefile must be clean.
- A clean polygon is one that has no self-intersections. This means that a segment belonging to one ring may not intersect a segment belonging to another ring. The rings of a polygon can touch each other at vertices but not along segments. Colinear segments are considered intersecting.
- A clean polygon is one that has the inside of the polygon on the *correct* side of the line that defines it. The neighborhood to the right of an observer walking along the ring in vertex order is the inside of the polygon. Vertices for a single, ringed polygon are, therefore, always in clockwise order.

Rings defining holes in these polygons have a counterclockwise orientation. *Dirty* polygons occur when the rings that define holes in the polygon also go clockwise, which causes overlapping interiors.

A sample polygon instance

The following figure shows a polygon with one hole and a total of eight vertices.

Figure E-1. A sample polygon

For this example, NumParts equals 2 and NumPoints equals 10. Note that the order of the points for the doughnut (hole) polygon is reversed below.

The following table shows Polygon byte stream contents

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	5	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$

Measured shape types in XY space

These topics describe shapes with X and Y coordinates that also have measure values.

PointM

A PointM consists of a pair of double-precision coordinates in the order X, Y, plus a measure M. The following table shows PointM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	21	Integer	1	Little endian

Position	Field	Value	Type	Number	Byte order
Byte 4	X	X	Double	1	Little endian
Byte 12	Y	Y	Double	1	Little endian
Byte 20	M	M	Double	1	Little endian

MultiPointM

The following fields are for a MultiPointM:

Box The bounding box for the MultiPointM, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts
The number of Points

NumPoints
An array of Points of length NumPoints

M Range
The minimum and maximum measures for the MultiPointM stored in the order Mmin, Mmax

M Array
An array of Measures of length NumPoints

The following table shows MultiPointM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	28	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumPoints	NumPoints	Integer	1	Little endian
Byte 40	Points	Points	Point	NumPoints	Little endian
Byte X	Mmin	Mmin	Double	1	Little endian
Byte X+8	Mmax	Mmax	Double	1	Little endian
Byte X+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 40 + (16 * \text{NumPoints})$.

PolyLineM

A shapefile PolyLineM consists of one or more parts. A part is a connected sequence of two or more points. Parts may or may not be connected to one another. Parts may or may not intersect one another.

The following fields are for a PolyLineM:

Box The bounding box for the PolyLineM stored in the order Xmin, Ymin, Xmax, Ymax

NumParts
The number of parts in the PolyLineM

NumPoints
The total number of points for all parts

Parts An array of length NumParts
Stores, for each part, the index of its first point in the points array. Array indexes are numbered with respect to 0.

Points An array of length NumPoints

The points for each part in the PolyLineM are stored end to end. The points for part 2 follow the points for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the points array between parts.

M Range

The minimum and maximum measures for the PolyLineM stored in the order Mmin, Mmax

M Array

An array of length NumPoints

The measures for each part in the PolyLineM are stored end to end. The measures for part 2 follow the measures for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the measure array between parts.

The following table shows PolyLineM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	23	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian
Byte Y	Mmin	Mmin	Double	1	Little endian
Byte Y+8	Mmax	Mmax	Double	1	Little endian
Byte Y+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$

PolygonM

A PolygonM consists of a number of rings. A ring is a closed, non-self-intersecting loop. Note that intersections are calculated in XY space, *not* in XYM space. A PolygonM may contain multiple outer rings. The rings of a PolygonM are referred to as its parts.

The following fields are for a PolygonM:

Box The bounding box for the PolygonM, stored in the order Xmin, Ymin, Xmax, Yma

NumParts

The number of rings in the PolygonM

NumPoints

The total number of points for all rings

Parts An array of length NumParts

Stores, for each ring, the index of its first point in the points array. Array indexes are numbered with respect to 0.

Points An array of length NumPoints

The points for each ring in the PolygonM are stored end to end. The points for Ring 2 follow the points for Ring 1, and so on. The parts array holds the array index of the starting point for each ring. There is no delimiter in the points array between rings.

M Range

The minimum and maximum measures for the PolygonM stored in the order Mmin, Mmax

M Array

An array of length NumPoints

The measures for each ring in the PolygonM are stored end to end. The measures for Ring 2 follow the measures for Ring 1, and so on. The parts array holds the array index of the starting measure for each ring. There is no delimiter in the measure array between rings.

The following are important notes about PolygonM shapes:

- The rings are closed (the first and last vertex of a ring must be the same).
- The order of rings in the points array is not significant.

The following table shows PolygonM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	15	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian
Byte Y	Mmin	Mmin	Double	1	Little endian
Byte Y+8	Mmax	Mmax	Double	1	Little endian
Byte Y+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$

Shape types in XYZ space

These topics describe shapes with X, Y, and Z coordinates.

PointZ

A PointZ consists of a triplet of double-precision coordinates in the order X, Y, Z.

The following table shows PointZ byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	9	Integer	1	Little endian
Byte 4	X	X	Double	1	Little endian
Byte 12	Y	Y	Double	1	Little endian
Byte 20	Z	Z	Double	1	Little endian

MultiPointZ

A MultiPointZ represents a set of PointZs, as follows:

- The bounding box is stored in the order Xmin, Ymin, Xmax, Ymax.

- The bounding Z range is stored in the order Zmin, Zmax.

The following table shows MultiPointZ byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	20	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumPoints	NumPoints	Integer	1	Little endian
Byte 40	Points	Points	Point	NumPoints	Little endian
Byte X	Zmin	Zmin	Double	1	Little endian
Byte X+8	Zmax	Zmax	Double	1	Little endian
Byte X+16	Z Array	Z Array	Double	NumPoints	Little endian

Tip: $X = 40 + (16 * \text{NumPoints})$

PolyLineZ

A PolyLineZ consists of one or more parts. A part is a connected sequence of two or more points. Parts may or may not be connected to one another. Parts may or may not intersect one another.

The following fields are for a PolyLineZ:

Box The bounding box for the PolyLineZ, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts
The number of parts in the PolyLineZ

NumPoints
The total number of points for all parts

Parts An array of length NumParts
Stores, for each part, the index of its first point in the points array.
Array indexes are numbered with respect to 0.

Points An array of length NumPoints
The points for each part in the PolyLineZ are stored end to end. The points for part 2 follow the points for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the points array between parts.

Z Range
The minimum and maximum Z values for the PolyLineZ stored in the order Zmin, Zmax

Z Array
An array of length NumPoints
The Z values for each part in the PolyLineZ are stored end to end. The Z values for part 2 follow the Z values for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the Z Array between parts.

The following table shows PolyLineZ byte stream contents

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	10	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian
Byte Y	Zmin	Zmin	Double	1	Little endian
Byte Y+8	Zmax	Zmax	Double	1	Little endian
Byte Y+16	Z Array	Z Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$

PolygonZ

A PolygonZ consists of a number of rings. A ring is a closed, non-self-intersecting loop. A PolygonZ may contain multiple outer rings. The rings of a PolygonZ are referred to as its parts.

The following fields are for a PolygonZ:

Box The bounding box for the PolygonZ stored in the order Xmin, Ymin, Xmax, Ymax

NumParts
The number of rings in the PolygonZ

NumPoints
The total number of points for all rings

Parts An array of length NumParts
Stores, for each ring, the index of its first point in the points array. Array indexes are numbered with respect to 0.

Points An array of length NumPoints
The points for each ring in the PolygonZ are stored end to end. The points for ring 2 follow the points for ring 1, and so on. The parts array holds the array index of the starting point for each ring. There is no delimiter in the points array between rings.

Z Range
The minimum and maximum Z values for the PolygonZ stored in the order Zmin, Zmax

Z Array
An array of length NumPoints
The Z values for each ring in the PolygonZ are stored end to end. The Z values for ring 2 follow the Z values for ring 1, and so on. The parts array holds the array index of the starting Z value for each ring. There is no delimiter in the Z value array between rings.

The following are important notes about PolygonZ shapes:

- The rings are closed (the first and last vertex of a ring must be the same).
- The order of rings in the points array is not significant.

The following table shows PolygonZ byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	19	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian
Byte Y	Zmin	Zmin	Double	1	Little endian
Byte Y+8	Zmax	Zmax	Double	1	Little endian
Byte Y+16	Z Array	Z Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$

Measured shape types in XYZ space

These topics describe shapes with X, Y, and Z coordinates that also have measure values.

PointZM

A PointZM consists of a quadruplet of double-precision coordinates in the order X, Y, Z, M.

The following table shows PointZM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	11	Integer	1	Little endian
Byte 4	X	X	Double	1	Little endian
Byte 12	Y	Y	Double	1	Little endian
Byte 20	Z	Z	Double	1	Little endian
Byte 28	M	M	Double	1	Little endian

MultiPointZM

A MultiPointZM represents a set of PointZMs, as follows:

- The bounding box is stored in the order Xmin, Ymin, Xmax, Ymax.
- The bounding Z range is stored in the order Zmin, Zmax.
- The bounding M range is stored in the order Mmin, Mmax.

The following table shows MultiPointZM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	18	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumPoints	NumPoints	Integer	1	Little endian
Byte 40	Points	Points	Point	NumPoints	Little endian
Byte X	Zmin	Zmin	Double	1	Little endian
Byte X+8	Zmax	Zmax	Double	1	Little endian
Byte X+16	Z Array	Z Array	Double	NumPoints	Little endian
Byte Y	Mmin	Mmin	Double	1	Little endian
Byte Y+8	Mmax	Mmax	Double	1	Little endian
Byte Y+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 40 + (16 * \text{NumPoints})$, $Y = X + 16 + (8 * \text{NumPoints})$

PolyLineZM

A PolyLineZM consists of one or more parts. A part is a connected sequence of two or more points. Parts may or may not be connected to one another. Parts may or may not intersect one another.

The following fields are for a PolyLineZM:

Box The bounding box for the PolyLineZM, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts

The number of parts in the PolyLineZM

NumPoints

The total number of points for all parts

Parts An array of length NumParts

Stores, for each part, the index of its first point in the points array.

Array indexes are numbered with respect to 0

Points An array of length NumPoints

The points for each part in the PolyLineZM are stored end to end. The points for part 2 follow the points for part 1, and so on. The parts array holds the array index of the starting point for each part. There is no delimiter in the points array between parts.

Z Range

The minimum and maximum Z values for the PolyLineZM stored in the order Zmin, Zmax

Z Array

An array of length NumPoints

The Z values for each part in the PolyLineZM are stored end to end. The Z values for part 2 follow the Z values for part 1, and so on. There is no delimiter in the Z Array between parts.

M Range

The minimum and maximum measures for the PolyLineZM stored in the order Mmin, Mmax

M Array

An array of length NumPoints

The measures for each part in the PolyLineZM are stored end to end. The measures for part 2 follow the measures for part 1, and so on. There is no delimiter in the measure array between parts.

The following table shows PolyLineZM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	13	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian

Position	Field	Value	Type	Number	Byte order
Byte Y	Zmin	Zmin	Double	1	Little endian
Byte Y+8	Zmax	Zmax	Double	1	Little endian
Byte Y+16	Z Array	Z Array	Double	NumPoints	Little endian
Byte Z	Mmin	Mmin	Double	1	Little endian
Byte Z+8	Mmax	Mmax	Double	1	Little endian
Byte Z+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$, $Z = Y + 16 + (8 * \text{NumPoints})$

PolygonZM

A PolyLineZM consists of a number of rings. A ring is a closed, non-self-intersecting loop. A PolyLineZM may contain multiple outer rings. The rings of a PolyLineZM are referred to as its parts.

The following fields are for a PolyLineZM:

Box The bounding box for the PolyLineZM, stored in the order Xmin, Ymin, Xmax, Ymax

NumParts

The number of rings in the PolyLineZM

NumPoints

The total number of points for all rings

Parts An array of length NumParts

Stores, for each ring, the index of its first point in the points array.

Array indexes are numbered with respect to 0.

Points An array of length NumPoints

The points for each ring in the PolyLineZM are stored end to end. The points for ring 2 follow the points for ring 1, and so on. The parts array holds the array index of the starting point for each ring. There is no delimiter in the points array between rings.

Z Range

The minimum and maximum Z values for the PolyLineZM are stored in the order Zmin, Zmax

Z Array

An array of length NumPoints

The Z values for each ring in the PolyLineZM are stored end to end. The Z values for ring 2 follow the Z values for ring 1, and so on. There is no delimiter in the Z value array between rings.

M Range

The minimum and maximum measures for the PolyLineZM stored in the order Mmin, Mmax

M Array

An array of length NumPoints

The measures for each ring in the PolyLineZM are stored end to end. The measures for ring 2 follow the measures for ring 1, and so on. There is no delimiter in the measure array between rings.

The following are important notes about PolyLineZM shapes:

- The rings are closed (the first and last vertex of a ring must be the same).
- The order of rings in the points array is not significant.

The following table shows PolyLineZM byte stream contents.

Position	Field	Value	Type	Number	Byte order
Byte 0	Shape Type	15	Integer	1	Little endian
Byte 4	Box	Box	Double	4	Little endian
Byte 36	NumParts	NumParts	Integer	1	Little endian
Byte 40	NumPoints	NumPoints	Integer	1	Little endian
Byte 44	Parts	Parts	Integer	NumParts	Little endian
Byte X	Points	Points	Point	NumPoints	Little endian
Byte Y	Zmin	Zmin	Double	1	Little endian
Byte Y+8	Zmax	Zmax	Double	1	Little endian
Byte Y+16	Z Array	Z Array	Double	NumPoints	Little endian
Byte Z	Mmin	Mmin	Double	1	Little endian
Byte Z+8	Mmax	Mmax	Double	1	Little endian
Byte Z+16	M Array	M Array	Double	NumPoints	Little endian

Tip: $X = 44 + (4 * \text{NumParts})$, $Y = X + (16 * \text{NumPoints})$, $Z = Y + 16 + (8 * \text{NumPoints})$

Appendix F. Values for the `geometry_type` column

The system table `geometry_columns` maps spatial data types to values in its `geometry_type` column. The following table shows valid entries for the `geometry_type` column and the shapes they represent.

Column value	Spatial data type
0	ST_Geometry
1	ST_Point
2	ST_Curve
3	ST_LineString
4	ST_Surface
5	ST_Polygon
6	ST_GeomCollection
7	ST_MultiPoint
8	ST_MultiCurve
9	ST_MultiLineString
10	ST_MultiSurface
11	ST_MultiPolygon

For information about spatial data types, see Chapter 2, “Spatial data types,” on page 2-1.

Appendix G. Error messages

Spatial DataBlade functions that generate any of these errors will abort. Likewise, if a Spatial DataBlade function is part of a transaction, the transaction also aborts. Error message parameters marked with percent signs—for example, are replaced with appropriate values in the actual message text.

Error messages and their explanations

USE01 **Unable to establish a connection in %FUNCTION%.**

Explanation: The IBM Informix server unexpectedly returned a null value instead of a connection handle when the function attempted to connect to the server. The function was unable to determine the exact cause of the error.

User response: If this error continues to occur, contact IBM Informix Technical Support for assistance.

7USE02 **Function %FUNCTION% is unable to allocate memory.**

Explanation: The function could not allocate the memory that it requires.

User response: Ensure that your hardware meets the minimum memory requirements specified in the IBM Informix installation guide. Also make sure that you have not overallocated memory to the IBM Informix server or other applications. Consider increasing the amount of your hardware physical memory.

USE03 **Invalid geometry in %FUNCTION%.**

Explanation: The parameters entered into the function have produced an invalid geometry.

User response: Check the parameters and review Chapter 2, “Spatial data types,” on page 2-1, for a description of valid geometry.

USE04 **Function %FUNCTION% not applicable to type %TYPE%.**

Explanation: An invalid geometry type was passed to the function. Valid geometry types are geometry, point, linestring, polygon, multipoint, multilinestring, and multipolygon.

User response: Resubmit the function with one of the valid geometry types.

USE05 **This function is not yet implemented.**

Explanation: The function has not been implemented

for the current release. However, it may be available in a future release.

USE06 **Unknown ESRI shape library error (%ERRCODE%) in %FUNCTION%.**

Explanation: Contact IBM Informix Technical Support for assistance. Please include this error number and any other related error messages and information from the \$INFORMIXDIR/online.log file. If you are using the Spatial DataBlade module in conjunction with ArcSDE from ESRI, please also include any related information from the \$SDEHOME/etc/sde.errlog file.

USE07 **Internal SAPI error. %SAPIFUNC% returned %RETVAl%. Failure in %FUNCNAME%.**

Explanation: An error has occurred in the SAPI subsystem of the IBM Informix server.

User response: Contact IBM Informix Technical Support.

USE08 **Nearest-neighbor queries require an index scan.**

Explanation: An attempt was made to use a nearest-neighbor function as a filter during a sequential scan of a table. This is not supported.

USE09 **Unknown or unsupported shape file type (%TYPE%) found in %FUNCTION%.**

Explanation: An unrecognized shapefile type was encountered.

User response: For more information about shapefile types, see “Shape type values” on page E-1.

USE10 **Unknown or unsupported OpenGIS WKB type (%TYPE%) found in %FUNCTION%.**

Explanation: An unrecognized OpenGIS well-known binary type was encountered. This version of the Spatial DataBlade only supports point, linestring,

polygon, multipoint, multilinestring, and multipolygon.

USE11 **Invalid SRID %SRID% or NULL in %FUNCTION%.**

Explanation: A spatial reference identifier must be an integer value greater than 0. Negative values, real numbers, and characters are invalid.

USE12 **Unknown or unsupported geometry type (%TYPE%) found in %FUNCTION%.**

Explanation: An unrecognized geometry type was encountered. If you are inserting spatial data in a binary format it may be corrupt or malformed.

USE13 **Spatial DataBlade not installed correctly: the spatial_references table does not exist.**

Explanation: The Spatial DataBlade was not able to access the `spatial_references` table because it could not be found.

User response: Review the installation instructions for the Spatial DataBlade module and, if necessary, recreate the `spatial_references` table.

USE14 **Unknown spatial reference identifier %SRID%.**

Explanation: The `sde.spatial_references` table contains a list of all valid spatial reference identifiers. The function attempted to create a geometry with an SRID that does not exist in this table.

User response: Either use an SRID that is already in the `sde.spatial_references` table or add the unknown SRID to the table.

USE15 **Invalid coordinate reference system object in function %FUNCTION%.**

Explanation: A programmatic error has occurred in the Spatial DataBlade.

User response: Contact IBM Informix Technical Support.

USE16 **Unable to get the geometry data pointer from the server in %FUNCTION%.**

Explanation: A programmatic error has occurred in the Spatial DataBlade.

User response: Contact IBM Informix Technical Support.

USE17 **Geometry verification failed.**

Explanation: An error has occurred while the Spatial DataBlade was verifying the topological correctness of a geometry.

User response: Contact IBM Informix Technical Support.

USE18 **Buffer operation failed.**

Explanation: The source geometry and buffer distance submitted to the buffer function would result in a buffer with coordinates that fall outside the coordinate system specified in the source geometry's spatial reference system.

USE19 **Coordinates out of bounds in %FUNCTION%.**

Explanation: The function has created a geometry with coordinates that fall outside the coordinate system.

User response: Review "The `spatial_references` table" on page 1-5 for information about selecting a coordinate system. Typically, this error occurs when the buffer function generates a geometry with coordinates that are beyond the source geometry's coordinate system, which the new geometry inherits.

You may need to adjust the false origin and system units for your data. Please refer to the description of the `ST_Transform()` function in Chapter 8, "Spatial functions," on page 8-1, for additional information.

USE20 **Invalid parameter in function %FUNCTION%.**

Explanation: One of the parameters passed to the function is invalid.

User response: Review the syntax of the function listed in Chapter 8, "Spatial functions," on page 8-1. Correct the invalid parameter and resubmit the function.

USE21 **Geometry integrity error in function %FUNCTION%.**

Explanation: An inconsistency has been detected in a geometry's internal data structure.

User response: If this error continues to occur, contact IBM Informix Technical Support for assistance.

USE22 **Too many points in feature.**

Explanation: Returned if the buffer function creates a feature that exceeds the maximum number of points specified as a parameter to the function.

User response: Increase the size of the maximum

number of points parameter and resubmit the function.

USE23 **Spatial reference conflict, %SRID1% vs %SRID2%.**

Explanation: The geometries passed to the function did not share the same spatial reference system.

User response: Convert one of the geometries to have the same spatial reference system as the other and resubmit the function.

USE24 **Incompatible geometries in function %FUNCTION%.**

Explanation: The function expected two geometries of a certain type and did not receive them.

User response: Review the syntax of the function described in Chapter 8, “Spatial functions,” on page 8-1, correct the geometry, and resubmit the function.

USE25 **Subscript %SUBSCRIPT% out of range in function %FUNCTION%.**

Explanation: The function has detected that the subscript entered is outside the allowable range of values. For instance, the `ST_PointN()` function returns the *n*th point identified by the index parameter. If a negative value, 0, or a number greater than the number of points in the source linestring were entered, this error message would be returned.

User response: Correct the subscript value and resubmit the function.

USE26 **Subtype mismatch: received subtype=%TYPE1%, expected subtype=%TYPE2%.**

Explanation: This error can occur when you try to insert a geometry of one subtype into a column of a different subtype, for example an `ST_Point` into an `ST_LineString` column.

User response: To insert more than one subtype into a column, make that a column of type `ST_Geometry`.

USE27 **Unknown or unsupported geometry data structure version (%VERSION%) found in %FUNCTION%.**

Explanation: Future versions of the Spatial DataBlade may not be able to interpret geometries stored using this version of the DataBlade module. Similarly, this version of the Spatial DataBlade may not be able to interpret geometries stored using a future version.

If an upgrade mechanism is provided with a new version of this DataBlade module, use it on your data as described in the release notes. If an upgrade mechanism is not provided, you must unload your

data with the old DataBlade module version and reload it with the new version.

USE28 **Invalid text in %FUNCTION%.**

Explanation: The text string entered with the well-known text representation function is invalid.

User response: Correct the string and resubmit the function. Refer to Appendix C, “OGC well-known text representation of geometry,” on page C-1, for a valid text string description.

USE29 **Unexpected system error in %FUNCTION%.**

Explanation: An internal error occurred while creating a geometry. The system was not able to determine why this error occurred.

User response: Contact IBM Informix Technical Support for assistance. Please include this error number and any other related error messages and information from the `$INFORMIXDIR/online.log` file. If you are using the Spatial DataBlade module in conjunction with ArcSDE from ESRI, please also include any related information from the `$SDEHOME/etc/sde.errlog` file.

USE30 **Overlapping polygon rings in %FUNCTION%.**

Explanation: The internal rings of a polygon may not overlap one another or the bounding external ring. Polygon rings may only intersect at a single point.

USE31 **Too few points for geometry type in %FUNCTION%.**

Explanation: The number of coordinates entered for the geometry was too few. Points and multipoints require a minimum of one point; linestrings and multilinestrings require a minimum of two points; and polygons and multipolygons require a minimum of four points.

USE32 **Polygon does not close in %FUNCTION%.**

Explanation: The first and last coordinates of a polygon ring must be the same. An exterior or interior ring did not close (did not have the same first and last coordinates).

USE33 **Interior ring not enclosed by exterior ring in %FUNCTION%.**

Explanation: The interior rings of a polygon must be inside the exterior rings. The interior ring was detected to be outside its exterior ring.

USE34 Polygon has no area in %FUNCTION%.

Explanation: The rings of a polygon must enclose an area. The first and last point of each polygon ring must be the same. A ring may not cross itself.

USE35 Polygon ring contains a spike in %FUNCTION%.

Explanation: Polygon rings contain spikes whenever coordinates other than the endpoints are the same. The boundary of a polygon must be a continuous ring or series of rings.

USE36 Multipolygon exterior rings overlap in %FUNCTION%.

Explanation: The exterior rings of a multipolygon must enclose independent areas. The exterior rings of each polygon of a multipolygon may not overlap. They may, however, intersect at a single point. Polygons whose intersection results in a linestring will automatically be merged after the intersecting linestring has been dissolved.

USE37 The geometry boundary is self-intersecting in %FUNCTION%.

USE38 The geometry has too many parts in %FUNCTION%.

Explanation: The string that defines the geometry has too many parts for its type. Points, linestrings, and polygons are single-part geometries. The string has defined more than one part for one of these geometries. If a multipart geometry is desired, use multipoint, multilinestring, or multipolygon.

USE39 Mismatched text string parentheses in %FUNCTION%.

Explanation: The parentheses of the text string defining the geometry do not match.

User response: For a description of the well-known text representation, review Appendix C, "OGC well-known text representation of geometry," on page C-1.

USE40 Unknown or unsupported ESRI entity type (%TYPE%) found in %FUNCTION%.

Explanation: The internal type representation is invalid.

User response: Contact ESRI Technical Support.

USE41 The projection string for your SRID is invalid in %FUNCTION%.

Explanation: The projection string stored in the `spatial_references` table was determined to be invalid.

User response: Compare the projection string with the valid projection strings listed in Appendix B, "OGC well-known text representation of spatial reference systems," on page B-1.

USE42 Nearest-neighbor queries are not supported by the current version of the server.

Explanation: Nearest-neighbor queries are supported by IBM Informix Version 9.3 and later.

USE43 %PARAM1% value must be less than %PARAM2% value.

Explanation: When executing the `SE_CreateSrid()` function, `xmin` must be less than `xmax` and `ymin` must be less than `ymax`.

USE44 Unknown OGIS WKB byte-order byte encountered in %FUNCTION%.

Explanation: An unrecognized OpenGIS well-known binary byte-order byte was encountered. This is the first byte of the geometry data input byte stream. Valid values are 0x00 (big endian) and 0x01 (little endian).

USE45 OGIS WKB geometry collection type is not supported.

Explanation: The OpenGIS collection type (7) is not supported by this version of the Spatial DataBlade module.

USE46 Incompatible coordinate reference systems in function %FUNCTION%.

Explanation: This error can occur when you attempt to transform geometries using the `ST_Transform()` function. The only allowable transformations in this version of the Spatial DataBlade module are:

- Between two UNKNOWN coordinate systems (that is, the `srttext` column in the `spatial_references` table for both SRIDs is "UNKNOWN")
- Between a projected coordinate system and an unprojected coordinate system, in which the underlying geographic coordinate systems are the same
- Between two projected coordinate systems, in which the underlying geographic coordinate systems are the same
- Between two coordinate systems with the same geographic coordinate system (that is, a difference in false origin or system unit only)

USE47 **Cannot create SE_Metadata lohandle file %NAME%. Check directory permissions.**

Explanation: The metadata lohandle file is created at the time the DataBlade module is registered in your database. This file is located in the directory \$INFORMIXDIR/extend/spatial.versno/metadata. The user who registers the DataBlade must have write permission on this directory.

If this error occurs after you have successfully registered the Spatial DataBlade module, you should correct the permissions on the metadata directory and then recreate the metadata lohandle file by running the following SQL statement:

```
execute function SE_MetadataInit();
```

USE48 **SE_Metadata lohandle file %FILE% not found, unreadable, or corrupt. Execute function SE_MetadataInit to reinitialize.**

Explanation: The purpose of the SE_Metadata lohandle file is to allow access to metadata by all parallelized functions of the Spatial DataBlade module. It can be restored by running the following SQL statement:

```
execute function SE_MetadataInit();
```

This will reread the **spatial_references** table, recreate a smart large object containing metadata, and re-create a file containing the large object handle for this smart large object.

USE49 **SE_MetadataTable is a read only table.**

Explanation: The SE_MetadataTable table is created and populated when the Spatial DataBlade module is registered.

User response: Do not attempt to modify this table in any way.

USE50 **Vertex not found in %FUNCTION%.**

Explanation: The specified vertex cannot be found in the original geometry.

User response: Verify that the X, Y, M, and Z values (if any) of the vertex to be updated or deleted exactly match.

USE51 **SE_Metadata smart blob is corrupt or unreadable.**

Explanation: Execute the SE_MetadataInit() function to repair the smart large object. To enable parallel data queries, a copy of the **spatial_references** table contents is stored in a smart large object. This smart large object is created when the Spatial DataBlade is registered and is synchronized with the **spatial_references** table by

means of triggers. If the smart large object is corrupted, it can be re-created by running the following SQL statement:

```
EXECUTE FUNCTION SE_MetadataInit();
```

USE52 **SE_Metadata memory cache is locked.**

Explanation: Execute the SE_MetadataInit() function to reinitialize the memory cache. For computational efficiency, a copy of the **spatial_references** table contents is cached in memory. This cache is shared by all sessions and access to it is controlled by a spinlock. If a session failed to release this lock, another session may not be able to obtain access.

User response: To forcibly reset the lock, run the following SQL statement:

```
EXECUTE FUNCTION SE_MetadataInit();
```

USE53 **Spatial datablade assert failure. File = %FILE%, line = %LINE%.**

Explanation: A programmatic error has occurred in the Spatial DataBlade module. Contact IBM Informix Technical Support.

USE54 **You must create a default sbspace before you can register the Spatial DataBlade.**

Explanation: When the Spatial DataBlade is registered, a small (8 KB) smart large object is created and stored in the default sbspace. Registration fails if there is no default sbspace. This smart large object can be moved to a non-default sbspace after registration is complete; instructions for moving it are provided in the release notes.

-674 **Routine (%FUNCTION%) cannot be resolved.**

Explanation: This error message is generally returned by the IBM Informix server whenever you try to apply the function to a non-supported type.

User response: Check the geometry type entered and resubmit the function.

Appendix H. Accessibility

IBM strives to provide products with usable access for everyone, regardless of age or ability.

Accessibility features for IBM Informix products

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in IBM Informix products. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers.
- The attachment of alternative input and output devices.

Keyboard navigation

This product uses standard Microsoft Windows navigation keys.

Related accessibility information

IBM is committed to making our documentation accessible to persons with disabilities. Our publications are available in HTML format so that they can be accessed with assistive technology such as screen reader software.

IBM and accessibility

See the *IBM Accessibility Center* at <http://www.ibm.com/able> for more information about the IBM commitment to accessibility.

Dotted decimal syntax diagrams

The syntax diagrams in our publications are available in dotted decimal format, which is an accessible format that is available only if you are using a screen reader.

In dotted decimal format, each syntax element is written on a separate line. If two or more syntax elements are always present together (or always absent together), the elements can appear on the same line, because they can be considered as a single compound syntax element.

Each line starts with a dotted decimal number; for example, 3 or 3.1 or 3.1.1. To hear these numbers correctly, make sure that your screen reader is set to read punctuation. All syntax elements that have the same dotted decimal number (for example, all syntax elements that have the number 3.1) are mutually exclusive alternatives. If you hear the lines 3.1 USERID and 3.1 SYSTEMID, your syntax can include either USERID or SYSTEMID, but not both.

The dotted decimal numbering level denotes the level of nesting. For example, if a syntax element with dotted decimal number 3 is followed by a series of syntax elements with dotted decimal number 3.1, all the syntax elements numbered 3.1 are subordinate to the syntax element numbered 3.

Certain words and symbols are used next to the dotted decimal numbers to add information about the syntax elements. Occasionally, these words and symbols might occur at the beginning of the element itself. For ease of identification, if the word or symbol is a part of the syntax element, the word or symbol is preceded by the backslash (\) character. The * symbol can be used next to a dotted decimal number to indicate that the syntax element repeats. For example, syntax element *FILE with dotted decimal number 3 is read as 3 * FILE. Format 3* FILE indicates that syntax element FILE repeats. Format 3* * FILE indicates that syntax element * FILE repeats.

Characters such as commas, which are used to separate a string of syntax elements, are shown in the syntax just before the items they separate. These characters can appear on the same line as each item, or on a separate line with the same dotted decimal number as the relevant items. The line can also show another symbol that provides information about the syntax elements. For example, the lines 5.1*, 5.1 LASTRUN, and 5.1 DELETE mean that if you use more than one of the LASTRUN and DELETE syntax elements, the elements must be separated by a comma. If no separator is given, assume that you use a blank to separate each syntax element.

If a syntax element is preceded by the % symbol, that element is defined elsewhere. The string following the % symbol is the name of a syntax fragment rather than a literal. For example, the line 2.1 %OP1 refers to a separate syntax fragment OP1.

The following words and symbols are used next to the dotted decimal numbers:

- ? Specifies an optional syntax element. A dotted decimal number followed by the ? symbol indicates that all the syntax elements with a corresponding dotted decimal number, and any subordinate syntax elements, are optional. If there is only one syntax element with a dotted decimal number, the ? symbol is displayed on the same line as the syntax element (for example, 5? NOTIFY). If there is more than one syntax element with a dotted decimal number, the ? symbol is displayed on a line by itself, followed by the syntax elements that are optional. For example, if you hear the lines 5 ?, 5 NOTIFY, and 5 UPDATE, you know that syntax elements NOTIFY and UPDATE are optional; that is, you can choose one or none of them. The ? symbol is equivalent to a bypass line in a railroad diagram.
- ! Specifies a default syntax element. A dotted decimal number followed by the ! symbol and a syntax element indicates that the syntax element is the default option for all syntax elements that share the same dotted decimal number. Only one of the syntax elements that share the same dotted decimal number can specify a ! symbol. For example, if you hear the lines 2? FILE, 2.1! (KEEP), and 2.1 (DELETE), you know that (KEEP) is the default option for the FILE keyword. In this example, if you include the FILE keyword but do not specify an option, default option KEEP is applied. A default option also applies to the next higher dotted decimal number. In this example, if the FILE keyword is omitted, default FILE(KEEP) is used. However, if you hear the lines 2? FILE, 2.1, 2.1.1! (KEEP), and 2.1.1 (DELETE), the default option KEEP only applies to the next higher dotted decimal number, 2.1 (which does not have an associated keyword), and does not apply to 2? FILE. Nothing is used if the keyword FILE is omitted.
- * Specifies a syntax element that can be repeated zero or more times. A dotted decimal number followed by the * symbol indicates that this syntax element can be used zero or more times; that is, it is optional and can be

repeated. For example, if you hear the line 5.1* data-area, you know that you can include more than one data area or you can include none. If you hear the lines 3*, 3 HOST, and 3 STATE, you know that you can include HOST, STATE, both together, or nothing.

Notes:

1. If a dotted decimal number has an asterisk (*) next to it and there is only one item with that dotted decimal number, you can repeat that same item more than once.
 2. If a dotted decimal number has an asterisk next to it and several items have that dotted decimal number, you can use more than one item from the list, but you cannot use the items more than once each. In the previous example, you can write HOST STATE, but you cannot write HOST HOST.
 3. The * symbol is equivalent to a loop-back line in a railroad syntax diagram.
- + Specifies a syntax element that must be included one or more times. A dotted decimal number followed by the + symbol indicates that this syntax element must be included one or more times. For example, if you hear the line 6.1+ data-area, you must include at least one data area. If you hear the lines 2+, 2 HOST, and 2 STATE, you know that you must include HOST, STATE, or both. As for the * symbol, you can repeat a particular item if it is the only item with that dotted decimal number. The + symbol, like the * symbol, is equivalent to a loop-back line in a railroad syntax diagram.

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
1623-14, Shimotsuruma, Yamato-shi
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Corporation
J46A/G4
555 Bailey Avenue
San Jose, CA 95141-1003
U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy,

modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.
